Introduction

- Individual-level analysis of resting-state functional connectivity (rs-FC) using large datasets demands considerations of computational efficiency.

- We evaluate the usability of rs-FC for the analysis of individual differences when moving nuisance regression to the ROI-level.

Methods

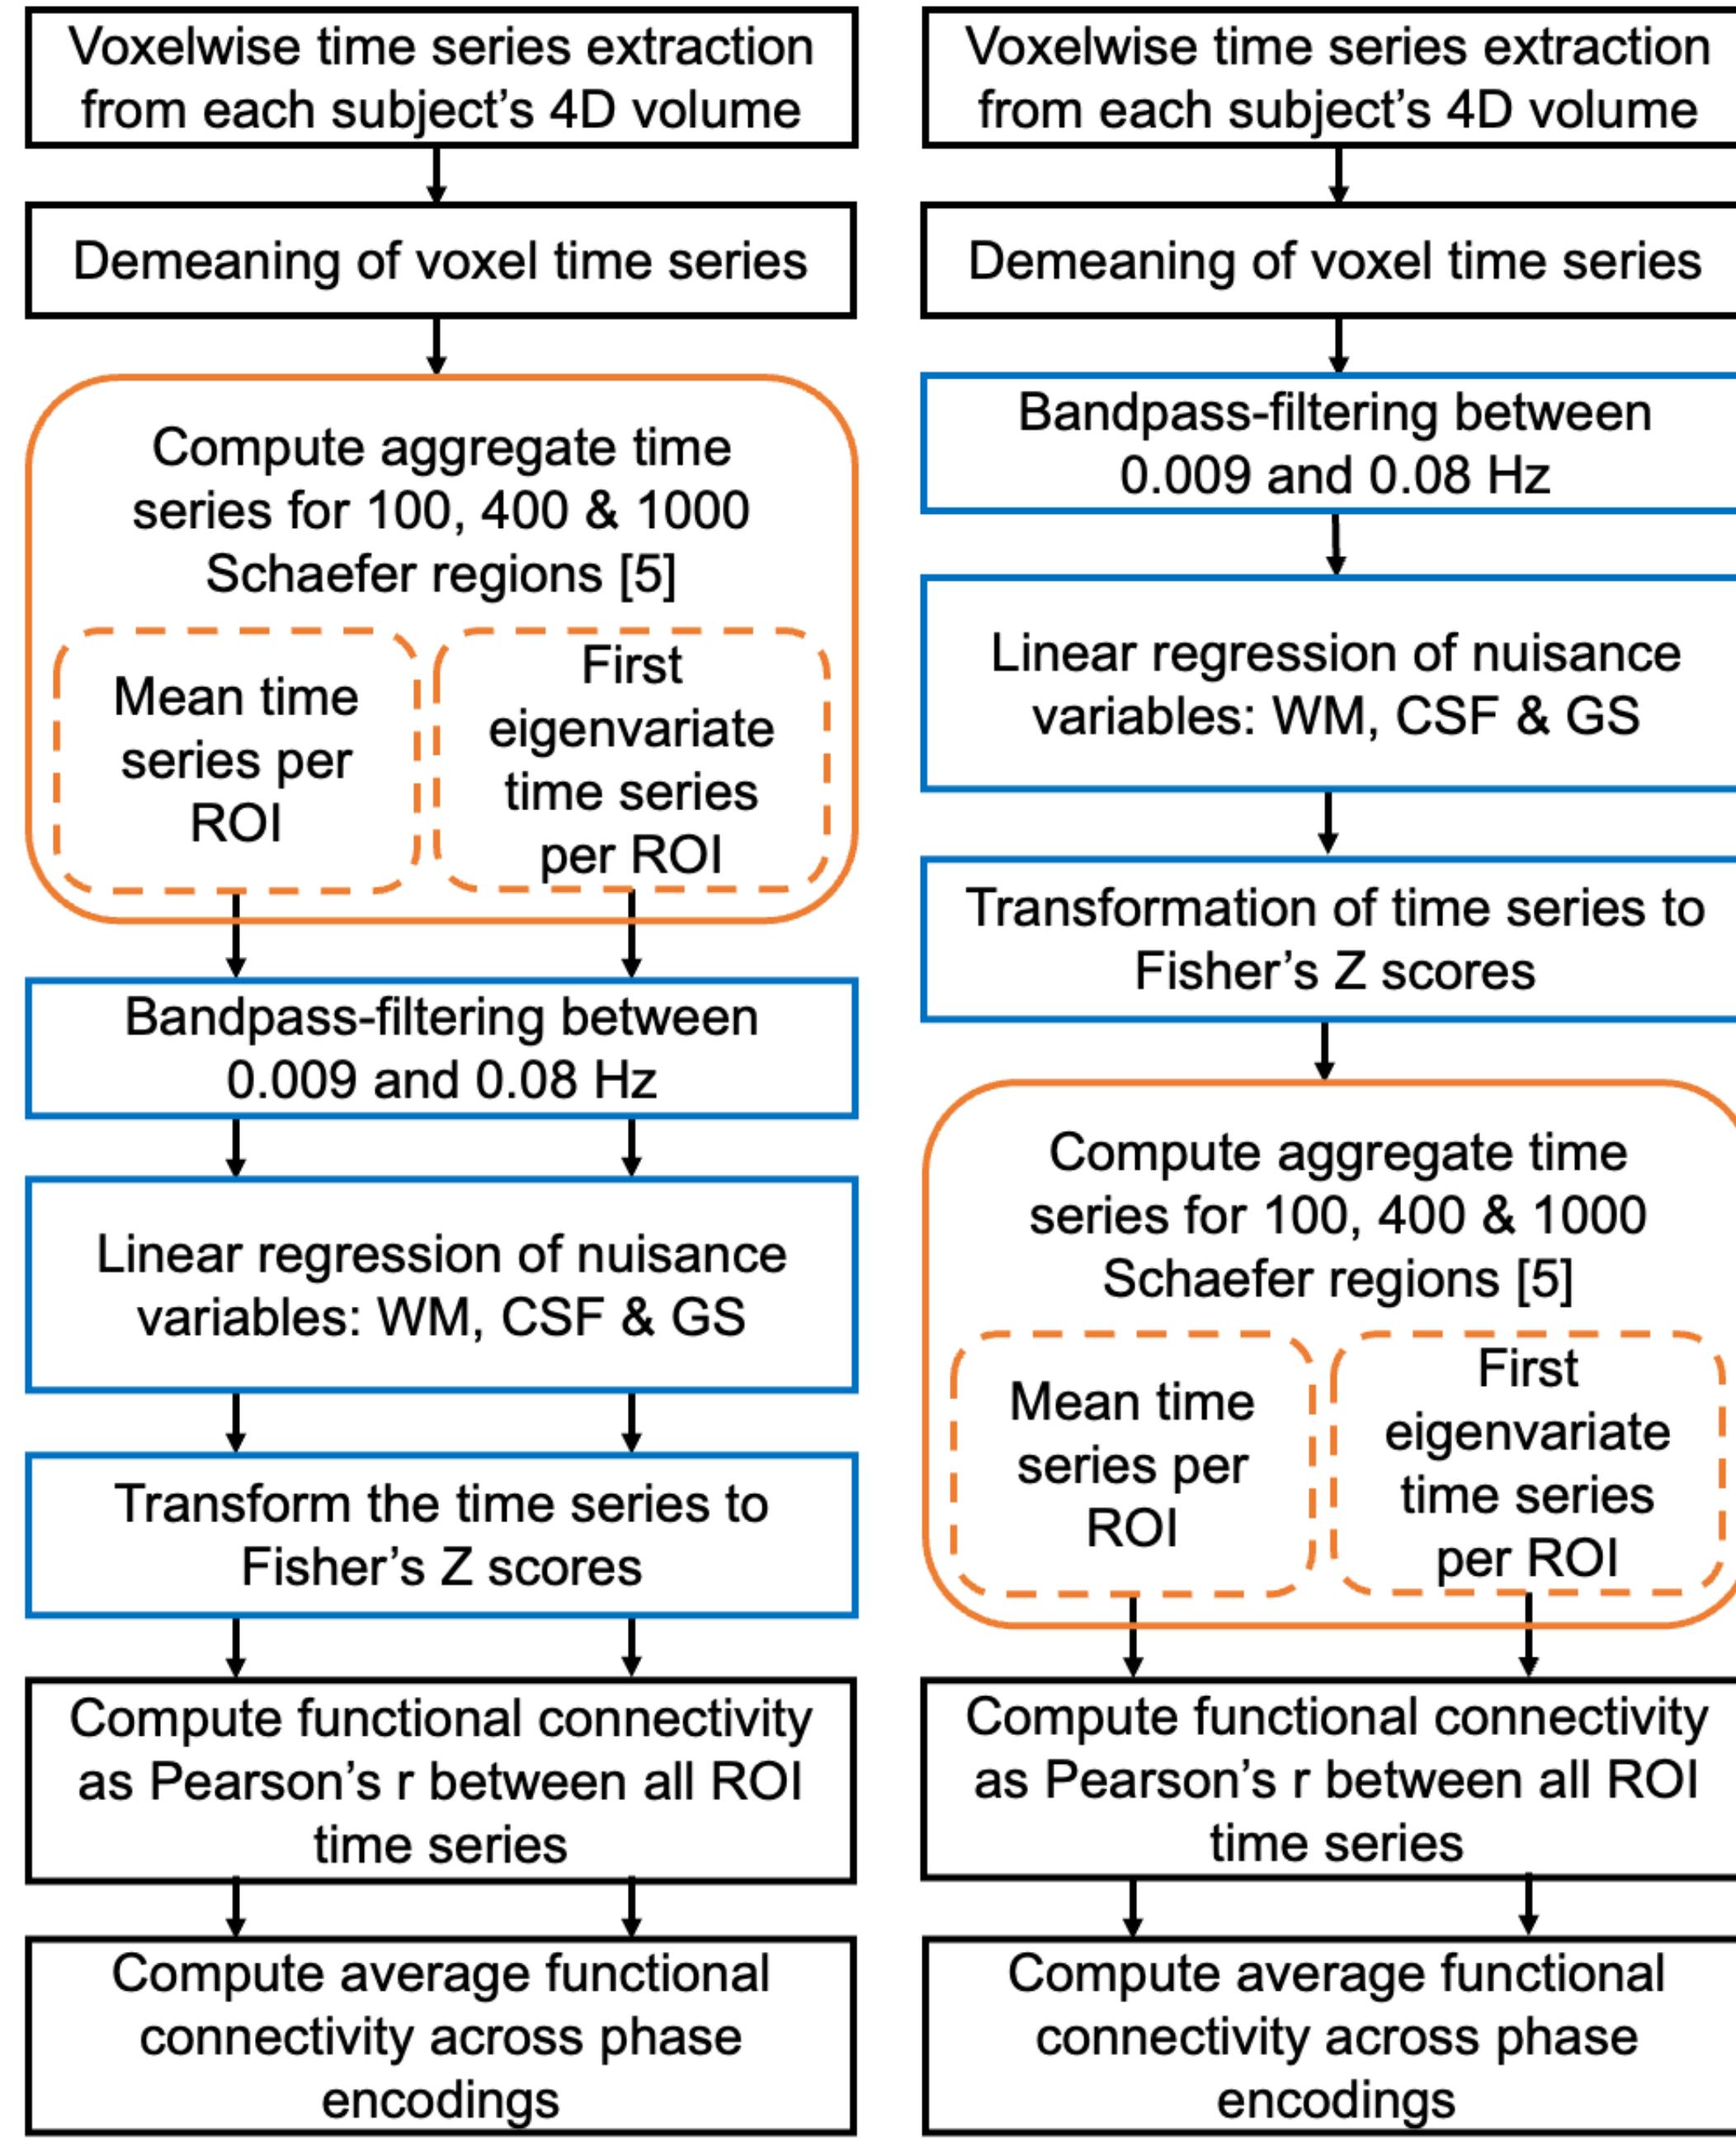

Fig. 1. Preprocessing pipelines for ROI- (left) & voxel-level cleaning (right).

- ICA-FIX cleaned data from 370 unrelated HCP-YA subjects [1, 2]
- Individual specificity assessed with FC identification accuracy [3] & differential identifiability [4]
- Individual-level prediction using Pearson kernel ridge regression & 5x5-fold CV

Results

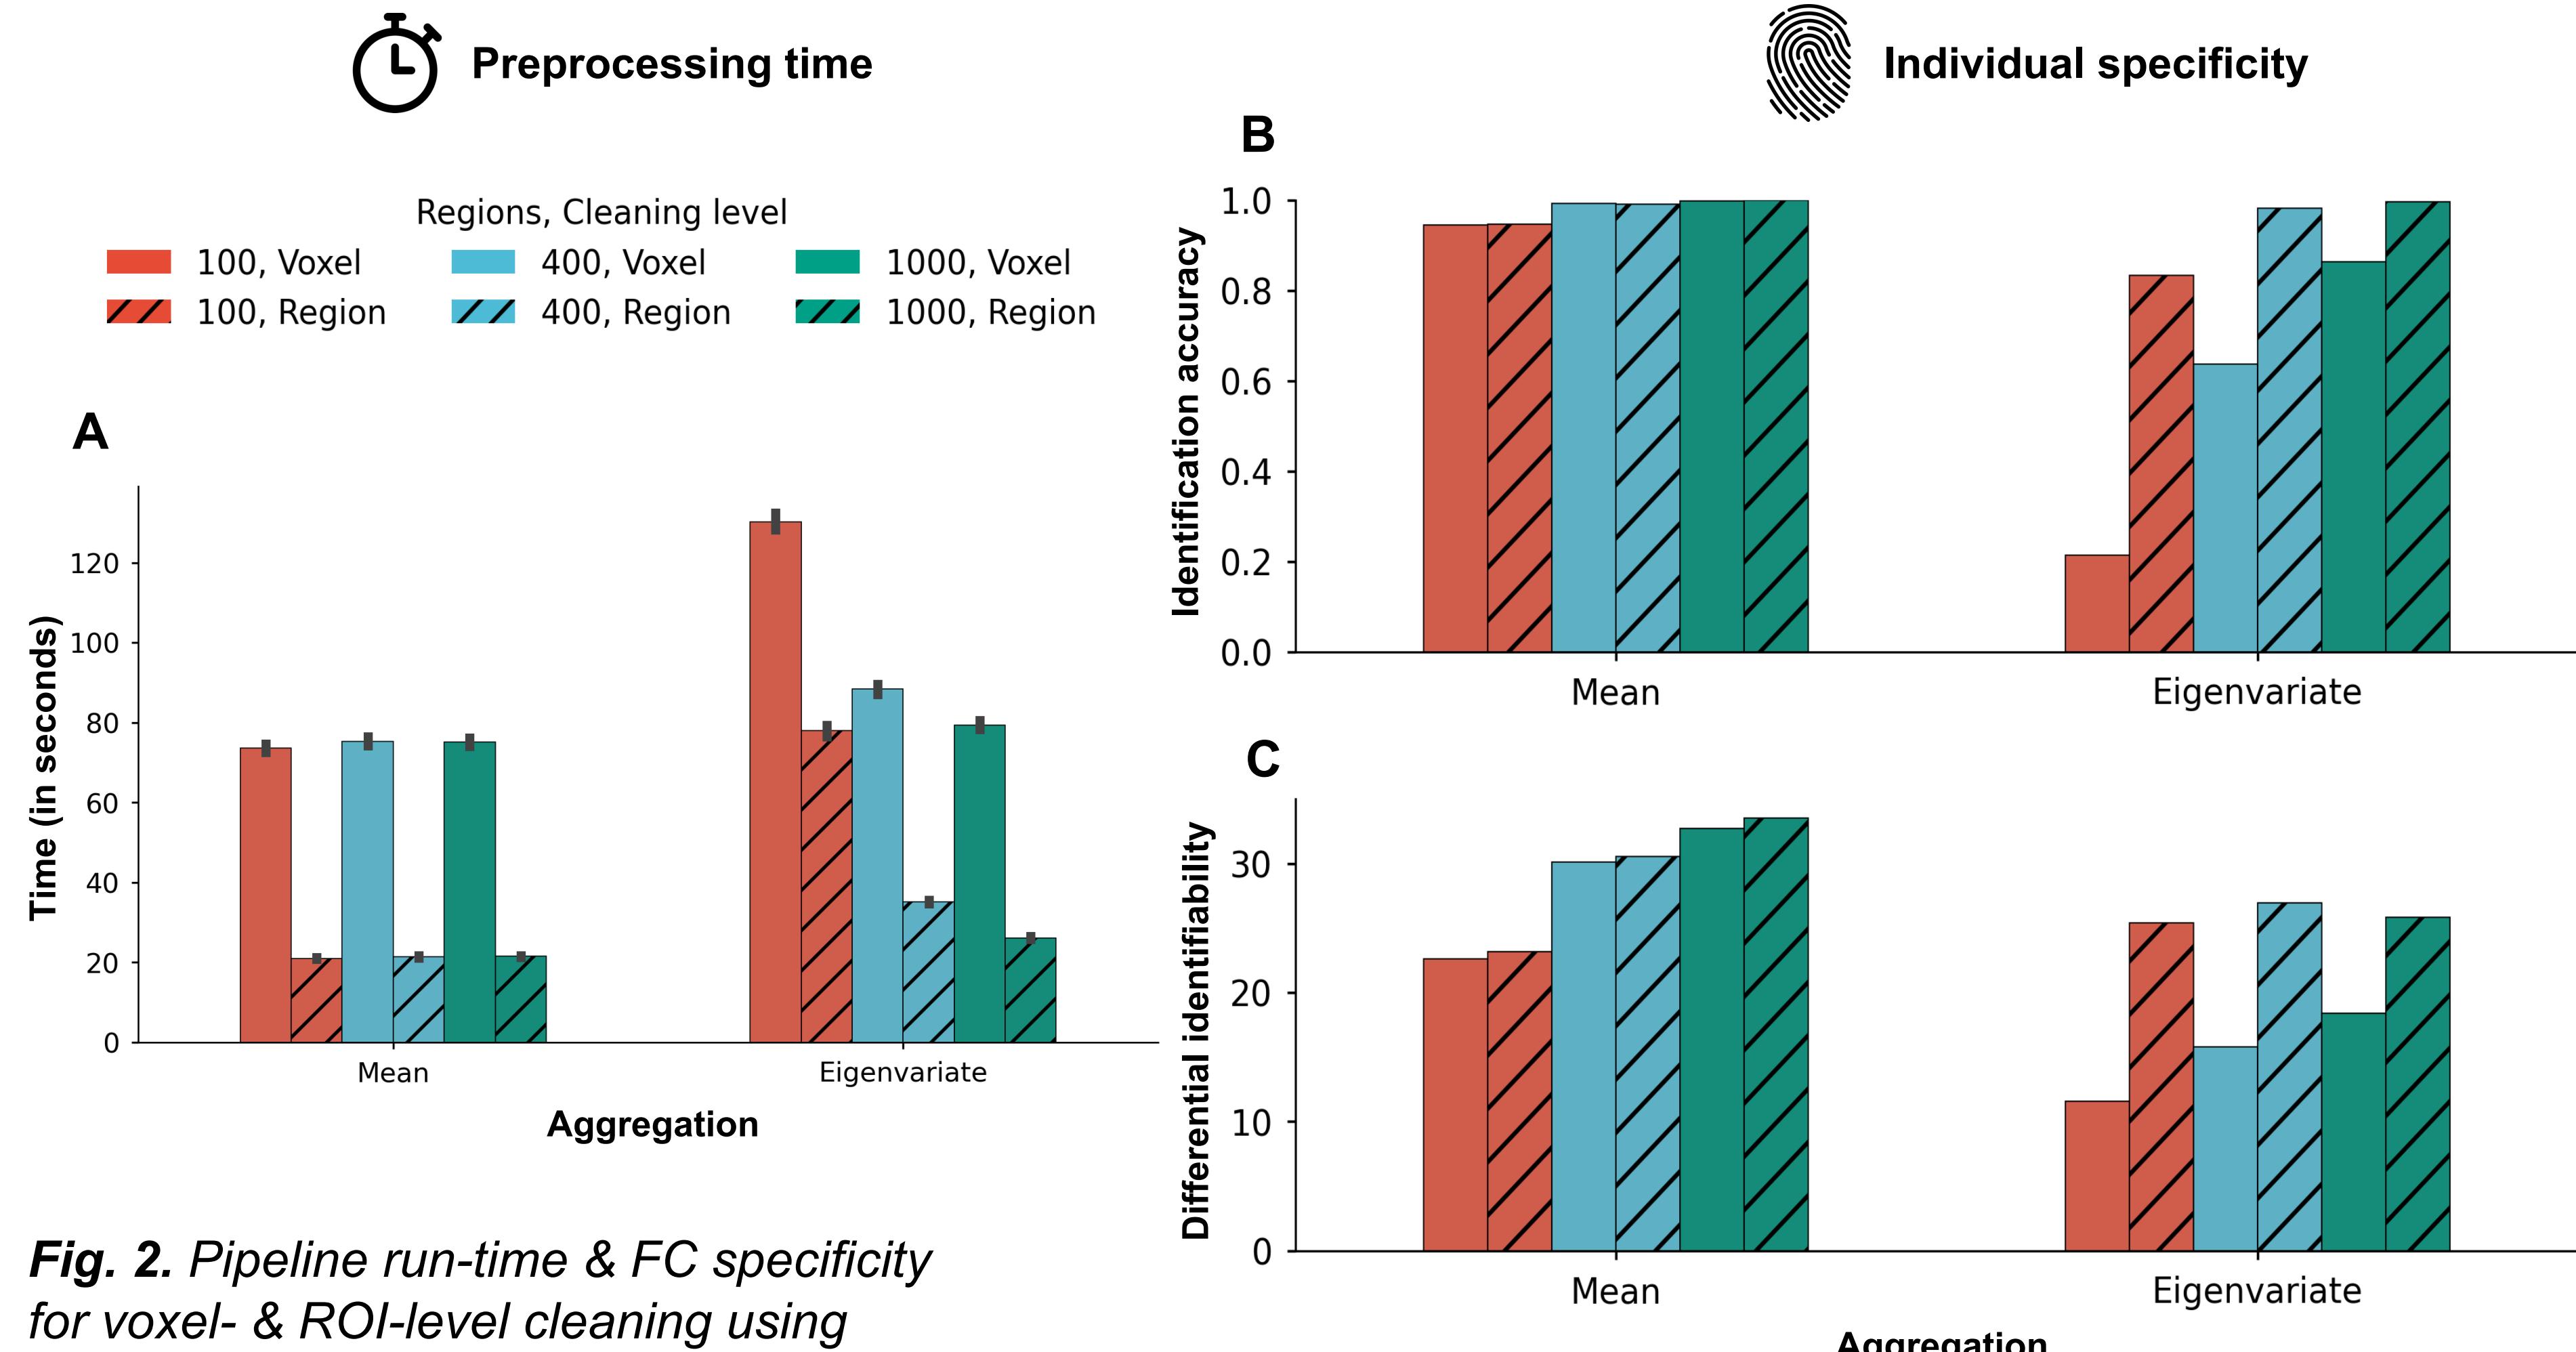

Fig. 2. Pipeline run-time & FC specificity for voxel- & ROI-level cleaning using Schaefer parcellation with 100-1000 regions.

A: Average computation time from time series extraction to FC generation was faster for ROI-level cleaning.
B & C: Individual specificity for mean aggregation equivalent between voxel- & ROI-level cleaning. First eigenvariate aggregation generates higher values in ROI-level cleaning.

Individual-level prediction

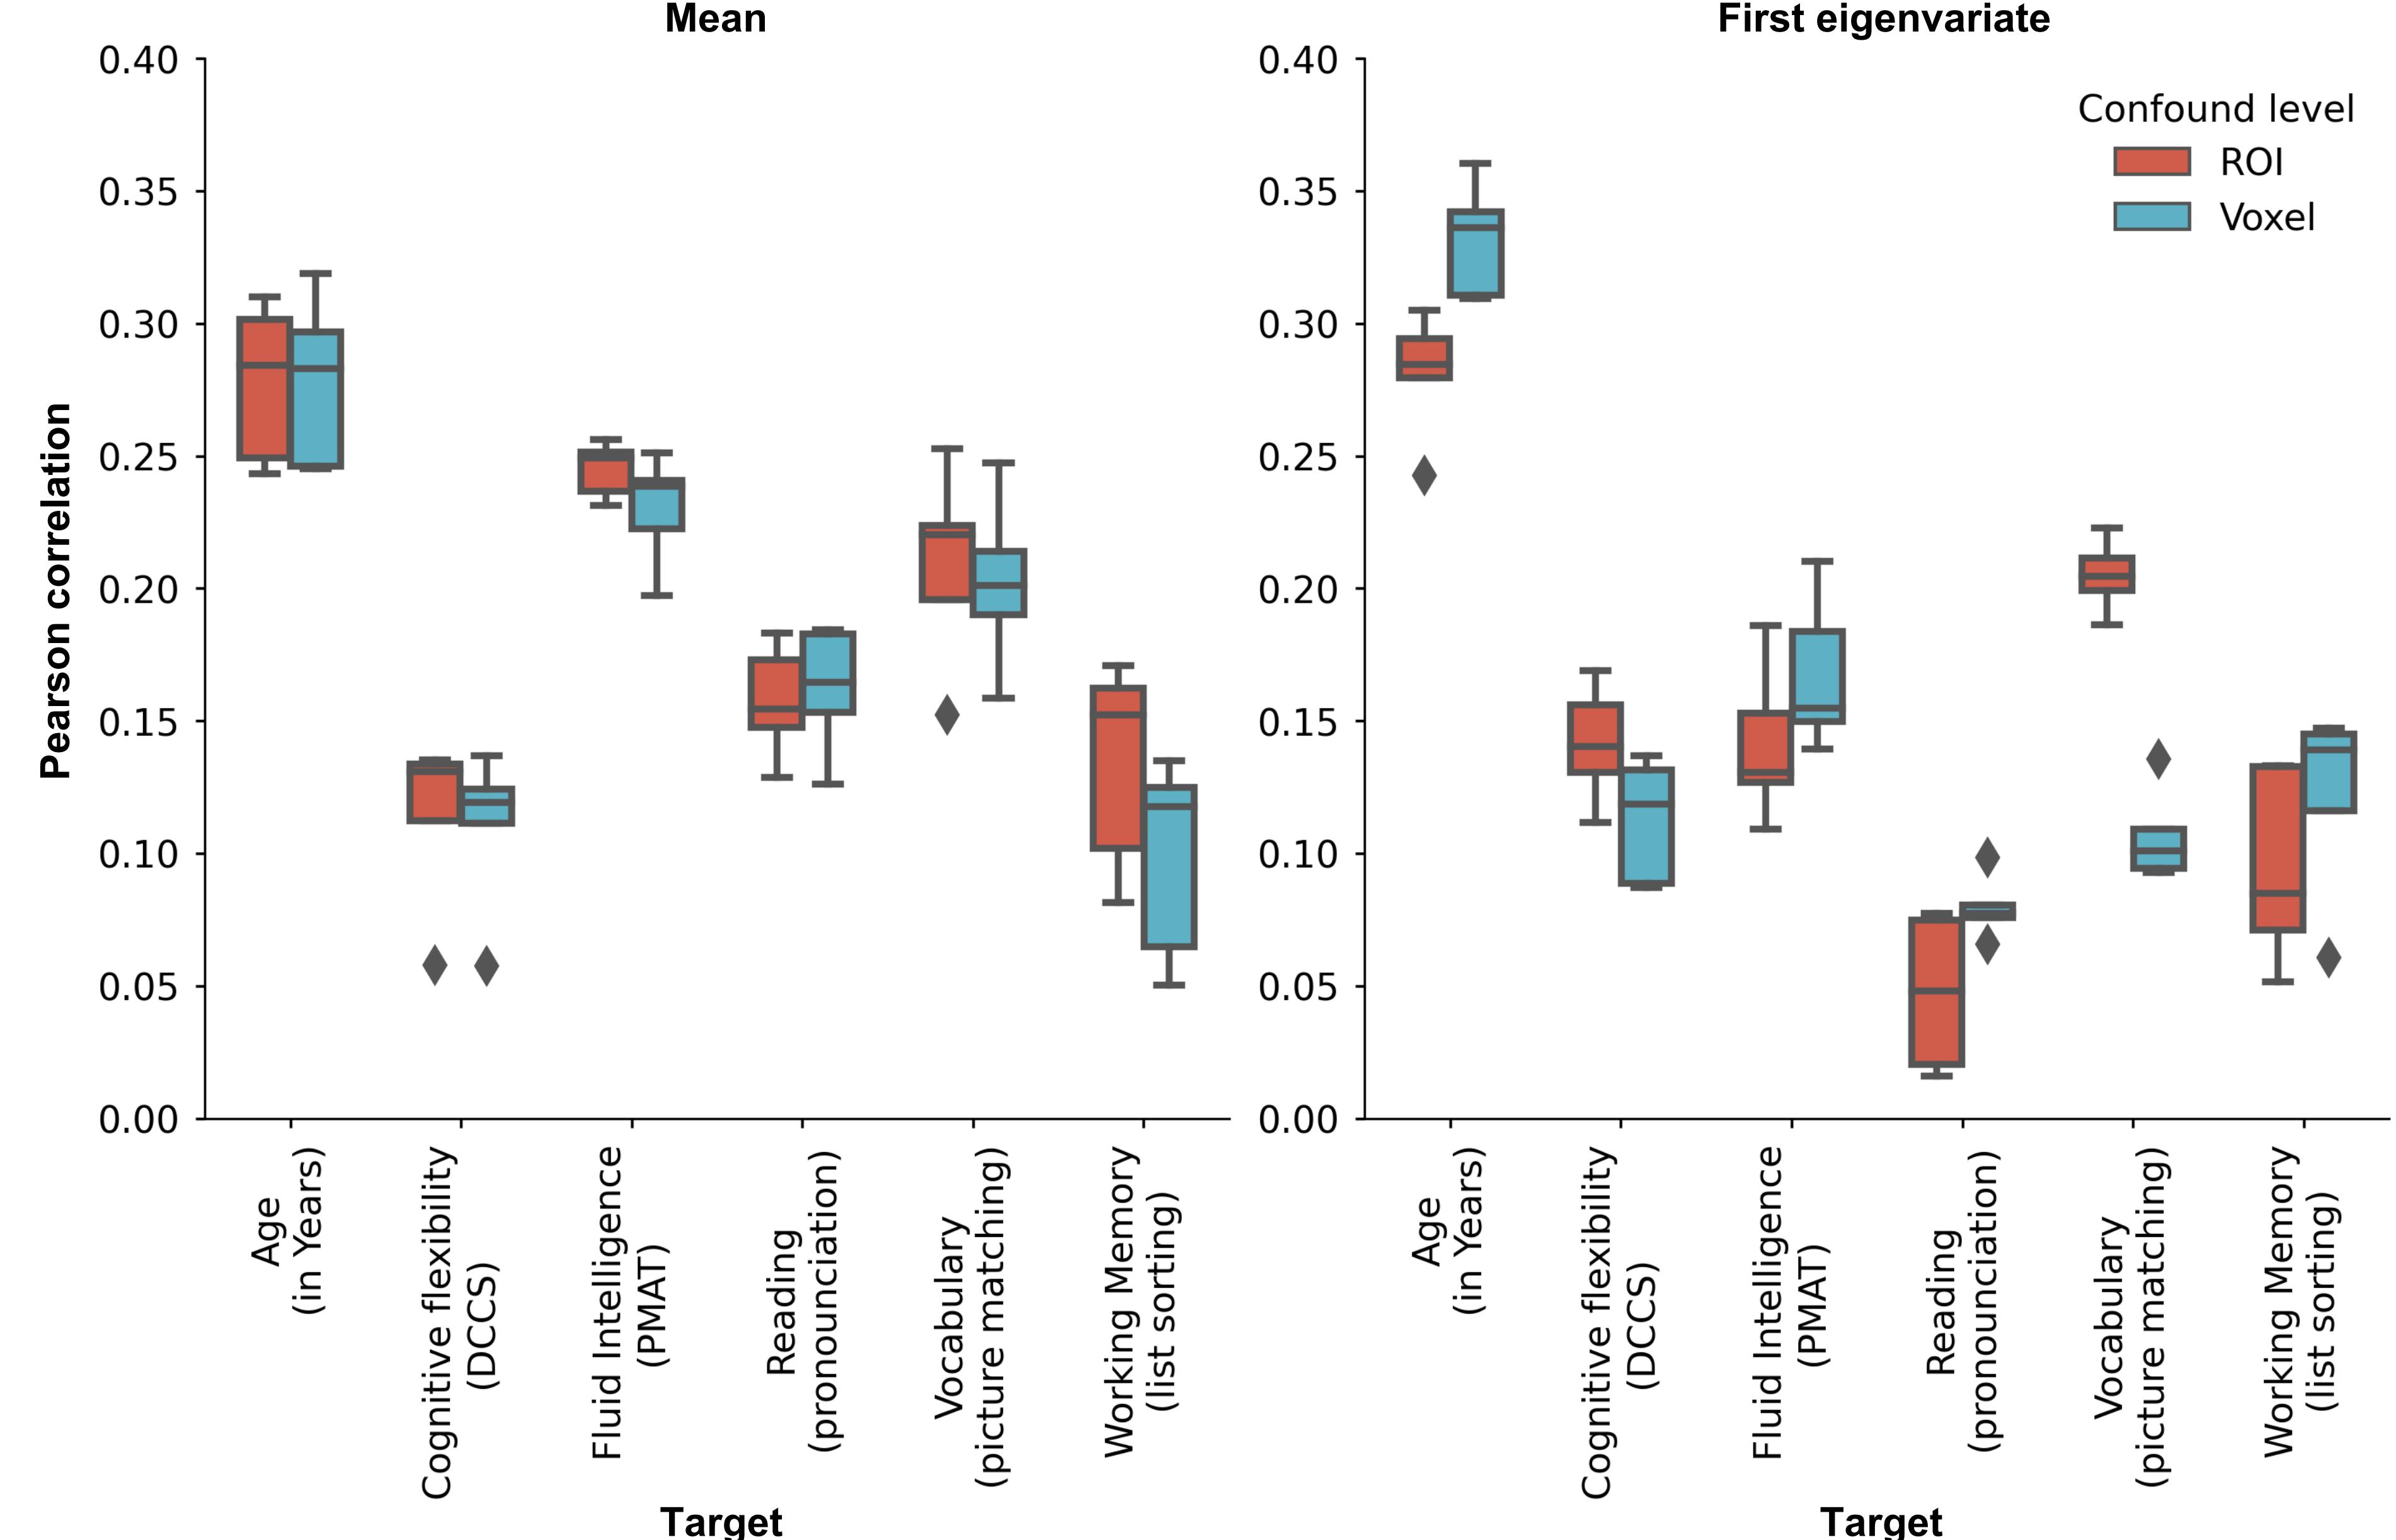

Fig. 3. Prediction scores (Pearson's r between predicted and observed values) for voxel- & ROI-level cleaned rs-FC averaged over sessions & using Schaefer parcellation with 400 regions. Scores using mean aggregation show equivalent scores for voxel- & ROI-level cleaning. First eigenvariate scores do not align well between voxel- & ROI-level. Higher scores in age, fluid intelligence, reading & working memory observed for voxel-level cleaning.

Discussion

Individual specificity

- ROI-level cleaning produced equivalent FC specificity values in the case of mean aggregation.
- ROI-level cleaning preserved more FC specificity when using first eigenvariate aggregation compared to voxel-level cleaning.

Individual-level prediction

- Mean aggregation led to similar prediction performance for all cognitive scores across both pipelines.
- Prediction from FC using first eigenvariate aggregation led to unequal prediction scores with no clear improvement.

Conclusion

- 3-fold decrease in computation time when switching to ROI-level cleaning using mean aggregation.
- No obvious recommendation for first eigenvariate aggregation.
