

# Neutron Protein Crystallography

DEVA workshop, Garching

17. November 2023 | [Tobias E. Schrader](#)

## Outline

- Motivation: Why do we need protein structures at atomic resolution?
- x-ray protein crystallography
- neutron protein crystallography
- Theory of scattering from crystals
- One or two application examples: From Structure to function...

# Proteine

- Etwa 20 000 verschiedene Proteine arbeiten im menschlichen Körper und erfüllen die unterschiedlichsten Aufgaben:

Hämoglobin,  
Sauerstofftransport

Rhodopsin,  
Sehvermögen

Insulin,  
Regulierung des  
Zuckerhaushalts

Alkoholdehydrogenase,  
Alkoholverdauung

Ribosom,  
Synthese von Proteinen

Einige von ihnen bieten Angriffspunkte für Medikamente...

# Enzyme sind biologische Katalysatoren

- Sie beschleunigen chemische Reaktionen schon nahe Raumtemperatur

- Temperatur ca. 37°C
- Hoch substrat-spezifisch

- Im Vergleich dazu:  
Chemische  
Industrie

- ❖ Oft hohe Temperaturen notwendig (=nicht sehr energieeffizient)
- ❖ Mitunter viele unerwünschte Nebenprodukte, die mühsam abgetrennt werden müssen

# Enzymes, a sub-class of proteins, accelerate chemical reactions

- ➡ very high substrate specificity
- ➡ rate enhancements up to  $10^{18}$
- ➡ enzymes can be “controlled”

# Some basics on protein structures

# Definition of the name "protein"

- Proteins are the most abundant class of biological macromolecules in all cellular organisms.
- They are polymers of  $\alpha$ -amino acids (2-amino carboxylic acids), formed by condensation of carboxyl and amino functions of adjacent units.

- Historical nomenclature:  
 $n < 10$ : oligopeptide  
 $10 < n < 100$ : polypeptide  
 $n > 100$ : protein
- Preferable: A protein is a polypeptide with a defined three-dimensional fold.

# Definition of dihedral angles

color code:  
 blue: nitrogen  
 red: oxygen  
 white: hydrogen  
 grey: carbon  
 green: symbol  
 for side chains

© Elsevier. Pollard et al: Cell Biology 2e - www.studentconsult.com

Per amino acid the peptide chain has these two dihedral angles as degrees of freedom.

# The 20 amino acids occurring in nature

- Side chains have different length and character
- $\alpha$ -Carbon is a chiral centre (exception: glycine)
- => D- and L-forms possible
- Cellular protein synthesis uses L-enantiomers only.

Proteins are chiral molecules!

# The hierarchy of protein architecture

- **Primary structure**

The sequence of amino acid residues (N to C terminus)

- **Secondary structure**

The local arrangement of main-chain atoms, often with specific hydrogen bonding pattern

- **Tertiary structure**

The packing of non-contiguous segments into a compact fold

- **Quaternary structure**

The association of individual chains into oligomeric structures

# Secondary structural elements

$\alpha$ -helix  
spiral conformation of a  
continuous chain

$\beta$ -sheet  
extended strands  
aligned side-by-side

turns / loops  
changing direction of  
chain

**Secondary structure** elements  
are generally stabilized by  
hydrogen bonds between different  
parts of the backbone of the protein.

© Elsevier, Pollard et al: Cell Biology 2e - www.studentconsult.com

# Not all dihedral angles are sterically allowed or favourable: The Ramachandran plot

© Garland Science 2010

# Tertiary structure: Fold classes

© Elsevier. Pollard et al: Cell Biology 2e - [www.studentconsult.com](http://www.studentconsult.com)

- Tertiary structure results from the arrangement of secondary structure elements self assembling into the native fold.
- This arrangement critically depends on side-chain interactions, the hydrophobic effect being a major driving force.

## Tertiary structure: sub-dividing the protein into domains

Secondary structure plot of human urokinase plasminogen activator receptor, a complex protein (pdb code 1YWH). The domains DI (yellow), DII (blue) and DIII (red) are shown. Amino acids not belonging to any domain are depicted in grey.

# What stabilizes the 3-dimensional fold: The protein folding problem

Unfolded states  $\rightleftharpoons$  Intermediate states  $\rightleftharpoons$  Native state(s)

- Polypeptide chains tend to collapse into compact structures.
- Major driving force is the **hydrophobic effect** (entropic contribution of the solvent).
- Forces stabilizing folded proteins:

## Non-covalent bonds

- Hydrogen bonds
- Electrostatic forces
- V. d. Waals contacts

## Covalent bonds

- Disulfides
- Isopeptide bonds

## Summary of the protein part

- Proteins consist of a chain of amino acids.
- There are 20 amino acids occurring in nature.
- Proteins show a special 3-D structure which is specific to their function

**Why do we need to measure protein structures?  
Are there no good simulations?  
How do we measure protein structures?**

# Why do we need experimental studies on proteins?

- **MD-Simulations** suffer from non-perfect force fields: Especially the **long range electrostatics** is not reproduced very well. But proteins use defined and structure related electrostatics to move the acidity constants of side chains in order to make them fulfill their tasks. MD-simulations cannot model **bond breaking** and forming very well since the quantum chemistry nature of this process is not included in the theoretical foundation of MD.
- **Ab initio quantum chemical calculations** are still **too demanding** to model the complete active centre of a protein (including its substrate)

# Most structures are obtained by x-ray crystallography, available neutron structures in protein data bank: ca. 100

<http://www.rcsb.org/>

Total number of structures: 134656

# Most structures are obtained by x-ray crystallography, available neutron structures in protein data bank: ca. 200

Entries in the protein data base as of 9th of May 2022

Isotropic B-factor or temperature factor is a measure of the mobility of an atom

$B (\text{\AA}^2) = 8\pi^2 \langle u^2 \rangle$ , where  $\langle u^2 \rangle$  is the mean square atomic displacement

# Protein crystallography in general, valid for both x-rays and neutrons as probes

# Crystallography: Overview over the process

Harma Brondijk, Crystal and Structural chemistry, Utrecht University

# How a typical protein crystal looks like...

Picture taken from Lecture of  
Prof. Locher at ETH Zürich

fig 2.2

**Protein crystals contain a lot of solvent and are held together by a limited number of weak contacts between protein molecules**

Acetylcholinesterase  
~68% solvent

β2 Glycoprotein I  
~90% solvent  
(extremely high!)

Typical solvent content 40-60%

Solvent channels allow diffusion of compounds into crystal

Often these compounds can reach the active or binding site

Often enzymes are active in crystalline state

# Size considerations of protein crystals

size:

**x-ray-crystallography:**

ca.  $10\text{ }\mu\text{m}$  x  $10\text{ }\mu\text{m}$  x  $10\text{ }\mu\text{m}$

typically cryoprotectants needed to facilitate measurements at low (80 K) temperatures

**neutron protein crystallography:**

The desirable size should be around  
 $1\text{ mm}$  x  $1\text{ mm}$  x  $1\text{ mm}$  (depending on the protein/space group)

Outer diameter of the glass tube: 5 mm

## Experimental set up (in case of x-rays but similar in the case of neutrons):

# Typical x-ray protein crystallography beamline: BL 14.2 at Bessy (Berlin) run by Manfred Weiss

length scale ca. 0.5 m

# Schematic overview over BioDiff: A neutron protein diffractometer: collaboration between JCNS and TUM (FRM-II)

**Bragg's law**

$$n\lambda = 2d \sin\theta$$

## BioDiff, the corresponding view in reality:

# Ewald construction and Bragg's Law

# Myoglobin protein crystal (deuterated mother liquor) full data set recorded with CCD

prim.  
beam

BioDiff: exposure time per frame: 20 minutes,  
sample: Myoglobin in deuterated mother liquor

## NIP-scanner

- larger solid angle
- readout time  $\geq 4$  min

## CCD-camera

- smaller solid angle
- readout time  $\geq 1$  sec

# Theory on scattering from a crystal

## 3D structural analysis:

$$\rho(x, y, z) = \frac{1}{V_E} \sum_{h,k,l} F_{hkl} \cdot e^{-2\pi i(h \cdot x + k \cdot y + l \cdot z)}$$

Structure factors are complex numbers:  $F_{hkl} = \|F_{hkl}\| e^{-2\pi i \alpha_{hkl}}$   
with amplitudes  $\|F_{hkl}\|$  and phases  $\alpha_{hkl}$

→ Phase Problem, because we only record intensities:  $I = \|F_{hkl}\|^2$

# The phases are stronger than the intensities

<http://www.ysbl.york.ac.uk/~cowtan/fourier/magic.html>

# Solving the phase problem

- Structures of <1000 atoms can be solved by brute force statistical *Direct Methods*, given data to 1.2 Å or better. Most small molecule structures are solved this way.
- A closely related known structure can be used as a search fragment for MR = *Molecular Replacement*.
- Heavy atoms can be introduced and the small changes in the reflection intensities exploited (SIR / MIR = Single / Multiple *Isomorphous Replacement*).
- Heavier atoms exhibit wavelength-dependent *Anomalous Scattering*, with the result that  $F_{hkl}$  and  $F_{-h-k-l}$  are not exactly equal. These small differences can be exploited in the Single Anomalous Diffraction and Multiple Anomalous diffraction (MAD) methods. For MAD, either metal atoms such as Fe present in the protein, or Se in selenomethionine (genetically modified methionine) are suitable anomalous scatterers.

# Flow chart of data treatment and model building

J. Biol. Chem. 2013, 288:4715-4722

- Proteins show a special 3-D structure which is specific to their function
- **x-ray crystallography**: Most of the beautiful schematic pictures of proteins in textbooks of chemistry and molecular biology represent structures determined by X-ray diffraction. Advantages:

1. only small crystals needed
2. short measurement times enable large throughput
3. phase problem can be solved with more and more sophisticated methods

Disadvantages:

1. radiation damage often observed: hydrogen abstraction, reduction of metal centres in the metallo-proteins, disulfide bond cleavage.
  2. Hydrogen positions can usually not be determined (only at high resolution)
- **Neutron protein crystallography** is a complementary technique as compared to x-ray crystallography. Here one can determine:
    1. protonation states of amino acid side chains (important for the function of the protein)
    2. deuterium exchange as a measure of flexibility and accessibility (discrimination between **H** / **D**)
    3. solvent structure including hydrogen atoms

## The R-Factors: Judging Convergence between model and data

To compare the generated electron density map and your model, you have to use the R-factor.

The R-factor is a measure of convergence between the intensities calculated from your model and the observed intensities.

$$R_{work} = \frac{\sum_{\mathbf{h}} \left| |F_{obs}(\mathbf{h})| - |F_{calc}(\mathbf{h})| \right|}{\sum_{\mathbf{h}} |F_{obs}(\mathbf{h})|}$$

**R:**

**0.6-VERY BAD**

**0.5 -BAD**

**0.4-Recoverable**

**0.2-Good for Protein**

**0.05-Good for small organic models**

**0-PERFECT FIT**

**However  $R_{work}$  can be reduced artificially by refining more parameters, so now it is usual to reserve 5 to 10% of the reflections to calculate an index  $R_{free}$  (same formula).**

**Table 1. Data collection statistics**

| Data collection                 | TAFI                   | TAFI-GEMSA             | TAFI-IIYQ              |
|---------------------------------|------------------------|------------------------|------------------------|
| Space group                     | P31 2 1                | P31 2 1                | P31 2 1                |
| Cell dimensions                 |                        |                        |                        |
| a, b, c, Å                      | 161.7, 161.7, 139.5    | 161.1, 161.1, 139.0    | 159.5, 159.5, 139.5    |
| $\alpha, \beta, \gamma, ^\circ$ | 90, 90, 120            | 90, 90, 120            | 90, 90, 120            |
| Resolution, Å                   | 49.51-3.10 (3.27-3.10) | 49.27-3.40 (3.58-3.40) | 49.03-2.80 (2.95-2.80) |
| $R_{\text{merge}}$              | 0.105 (0.833)          | 0.091 (0.630)          | 0.067 (0.600)          |
| $I / \sigma I$                  | 13.9 (2.6)             | 11.4 (2.2)             | 13.8 (2.1)             |
| Completeness, %                 | 100.0 (100.0)          | 99.6 (100.0)           | 100.0 (100.0)          |
| Redundancy                      | 8.6 (8.7)              | 4.9 (5.0)              | 4.3 (4.4)              |

Values in parentheses are for highest-resolution shell. A single crystal was used for each structure.

**Table 2. Refinement statistics**

| Refinement                          | TAFI          | TAFI-GEMSA    | TAFI-IIYQ     |
|-------------------------------------|---------------|---------------|---------------|
| Resolution, Å                       | 3.1           | 3.4           | 2.8           |
| No. reflections                     | 36638         | 27424         | 48058         |
| $R_{\text{work}} / R_{\text{free}}$ | 0.204 / 0.240 | 0.203 / 0.258 | 0.188 / 0.232 |
| No. atoms                           |               |               |               |
| Protein                             | 9861          | 9892          | 9901          |
| Ligand/ion                          | 0 / 3         | 45 / 3        | 36 / 3        |
| B-factors, Å <sup>2</sup>           |               |               |               |
| Protein                             | 94.8          | 113.3         | 67.5          |
| Ligand/ion                          | — / 102.9     | 111.9 / 117.5 | 72.4 / 71.3   |
| R.m.s. deviations                   |               |               |               |
| Bond lengths, Å                     | 0.018         | 0.013         | 0.018         |
| Bond angles, °                      | 1.751         | 1.453         | 1.871         |

— Indicates not applicable.

## Judging the quality of the data:

- $I/\sigma = \text{signal/noise} > 2.0$
- Completeness > 90%
- $R/R_{\text{free}}$ : difference < 0.05,
- Deviations of known geometry: weird angles

Isotropic B-factor or temperature factor is a measure of the mobility of an atom

The precision of the atomic model is mainly determined by the maximal resolution to which the crystal diffracts X-rays

Atomic resolution

## Look at B-factor distribution!

### Protein coloured by B-factor:

Well defined regions have low B-factors (blue/green)

Poorly defined/more mobile regions have high B-factors (yellow/orange/red)

# A protein molecule is dynamic

- The electron density is a spatial average over all molecules in the crystal and a time average over the duration of the X-ray data measurement
- => Multiple discrete conformations of a residue in different molecules are superimposed.
- A crude description of dynamics is provided in the pdb file as the isotropic B-factor
  - Some dynamical aspects evident in the electron density are lost in the pdb file

# Starting situation: You would like to do the neutron data refinement of Trypsin with the ligand Aminopyridin

What you have:

- A .sca file from the instrument responsible with the data (hkl, intensities, errors of intensities, the unit cell and the space group)
- A starting model from the pdb (may be a close by x-ray model)

# Starting model without the ligand

Protein data bank: [www.rcsb.org](http://www.rcsb.org)

The screenshot shows the RCSB PDB website interface. The browser address bar displays <https://www.rcsb.org/structure/5MNE>. The website header includes navigation links like Deposit, Search, Visualize, Analyze, Download, Learn, and More. The main content area features the PDB logo and a search bar. Below the search bar, there are tabs for Structure Summary, 3D View, Annotations, Sequence, Sequence Similarity, Structure Similarity, and Experiment. The 3D View tab is selected, showing a 3D ribbon diagram of the protein structure. To the right of the diagram, the entry details for 5MNE are displayed, including the title 'Cationic trypsin in its apo form (deuterated sample at 100 K)', DOI, classification as a hydrolase, and organism as Bos taurus. Below the details, there is an 'Experimental Data Snapshot' section and a 'wwPDB Validation' section with a bar chart showing various metrics and their percentile ranks.

**5MNE**  
Cationic trypsin in its apo form (deuterated sample at 100 K)  
DOI: [10.2210/pdb5MNE/pdb](https://doi.org/10.2210/pdb5MNE/pdb)  
Classification: [HYDROLASE](#)  
Organism(s): [Bos taurus](#)  
Deposited: 2016-12-13 Released: 2018-01-17  
Deposition Author(s): [Schiebel, J.](#), [Heine, A.](#), [Klebe, G.](#)  
Funding Organization(s): European Research Council

**Experimental Data Snapshot**  
Method: X-RAY DIFFRACTION  
Resolution: 1.008 Å  
R-Value Free: 0.125  
R-Value Work: 0.106

**wwPDB Validation**

| Metric                | Percentile Ranks | Value |
|-----------------------|------------------|-------|
| Rfree                 |                  | 0.125 |
| Clashscore            |                  | 3     |
| Ramachandran outliers |                  | 0     |
| Sidechain outliers    |                  | 0     |
| RSRZ outliers         |                  | 2.2%  |

## What do you need?

- The Software phenix.refine in its latest version:  
<https://www.phenix-online.org/download/>
- The Software Coot:  
<https://www2.mrc-lmb.cam.ac.uk/personal/pemsley/coot/>
- A two mouse button wheel mouse
- A good editor for text
- Some patience

# A tribute to the software programmers...

phenix.refine:

Afonine P.V., Grosse-Kunstleve R.W., Echols N., Headd J.J., Moriarty N.W., Mustyakimov M., Terwilliger T.C., Urzhumtsev A., Zwart P.H., & Adams P.D. (2012). *Acta Crystallogr D Biol Crystallogr* 68, 352-67.

## My advice

1. Always look at the maps and difference maps produced by each refinement step
2. Disregard refinement steps when r- factors increase or the difference between r-work and r-free gets too large (more than 2.5%)
3. Always look at the output pdb model with an editor of your own choice
4. Use the pdb checking tools by phenix and later from the web-site [www.rcsb.org](http://www.rcsb.org)

# Tutorial: Inhibitor binding to trypsin: charges shift protonation

→ question: inhibitors with less basic properties become protonated upon binding ?

Group of Prof. G. Klebe (Univ. Marburg)

Schiebel J. et al., Angewandte Chemie Int. Edition (2017), 56 (17):4887-4890

## Final results

Refinement is never finished!

Result without ligand aminopyridin

Result with the published structure in

# Proteins or structured macromolecules come in different shapes and sizes
