Abstract

The SU(3) flavour symmetry breaking expansion in up, down and strange quark masses is extended from hadron masses to meson decay constants. This allows a determination of the ratio of kaon to pion decay constants in QCD. Furthermore when using partially quenched valence quarks the expansion is such that SU(2) isospin breaking effects can also be determined. It is found that the lowest order SU(3) flavour symmetry breaking expansion (or Gell-Mann–Okubo expansion) works very well. Simulations are performed for 2 + 1 flavours of clover fermions at four lattice spacings.

1. Introduction

One approach to determine the ratio $|V_{us}/V_{ud}|$ of Cabibbo–Kobayashi–Maskawa (CKM) matrix elements, as suggested in [1], is by using the ratio of the experimentally determined pion and kaon leptonic decay rates

$$\frac{\Gamma(K^+ \to \mu^+ \nu_\mu)}{\Gamma(\pi^+ \to \mu^+ \nu_\mu)} = \frac{|V_{us}|^2}{|V_{ud}|^2} \left( \frac{f_{K^+}}{f_{\pi^+}} \right)^2 \left( \frac{M_{K^+}}{M_{\pi^+}} \right)^2 \left( \frac{1 - m_{\mu}^2/M_{K^+}^2}{1 - m_{\mu}^2/M_{\pi^+}^2} \right)^2 (1 + \delta_{em})$$

(1)

(where $M_{K^+}$, $M_{\pi^+}$ and $m_{\mu}$ are the particle masses, and $\delta_{em}$ is an electromagnetic correction factor). This in turn requires the determination of the ratio of kaon to pion decays constants, $f_{K^+}/f_{\pi^+}$, a non-perturbative task, where the lattice approach to QCD may be of help. For some recent work see, for example, [2–10].

The QCD interaction is flavour-blind and so when neglecting electromagnetic and weak interactions, the only difference between the quark flavours comes from the mass matrix. In this article we want to examine how this constrains meson decay matrix elements once full SU(3) flavour symmetry is broken, using the same methods as we used in [11,12] for hadron masses. In particular we shall consider pseudoscalar decay matrix elements and give an estimation for $f_{K}/f_{\pi}$ and $f_{K^+}/f_{\pi^+}$ (ignoring electromagnetic contributions).

2. Approach

In lattice simulations with three dynamical quarks there are many paths to approach the physical point where the quark masses take their physical values. The choice adopted here is to extrapolate from a point on the SU(3) flavour symmetry line keeping the singlet quark mass $m$ constant, as illustrated in the left panel of
for the case of two mass degenerate quarks $m_u = m_d \equiv m_0$. This allows the development of an SU(3) flavour symmetry breaking expansion for hadron masses and matrix elements, i.e. an expansion in

$$\delta m_q = m_q - \bar{m}, \quad \text{with} \quad \bar{m} = \frac{1}{2}(m_u + m_d + m_s)$$

(2)

where numerically $\bar{m} = m_0$. From this definition we have the trivial constraint

$$\delta m_u + \delta m_d + \delta m_s = 0.$$  

(3)

The path to the physical quark masses is called the ‘unitary line’ as we expand in the same masses for the sea and valence quarks. Note also that the expansion coefficients are functions of $\bar{m}$ only, which provided we keep $\bar{m} =$ const. reduces the number of allowed expansion coefficients considerably.

As an example of an SU(3) flavour symmetry breaking expansion, [12], we consider the pseudoscalar masses, and find to next-to-leading-order, NLO, (i.e. $O((\delta m_q)^2)$)

$$M^2(a\bar{b}) = M^2_0 + \alpha(\delta m_u + \delta m_b)$$

$$+ \beta_1 \frac{1}{2}(\delta m_u^2 + \delta m^2_0 + \delta m_b^2)$$

$$+ \beta_2 (\delta m_u^2 + \delta m_b^2) + \beta_3 (\delta m_u - \delta m_b)^2$$

$$+ \ldots.$$  

(4)

where $m_u, m_b$ are quark masses with $a, b = u, d, s$. This describes the physical outer ring of the pseudoscalar meson octet (the right panel of Fig. 1). Numerically we can also in addition consider a fictitious particle, where $a = b = s$, which we call $\eta_s$. We have further extended the expansion to the next-to-next-to-leading or NNLO case, [13]. As the expressions start to become unwieldy, they have been relegated to Appendix A. (Octet baryons also have equivalent expansions, [13].)

The vacuum is a flavour singlet, so meson to vacuum matrix elements $\langle 0 | \bar{Q} | M \rangle$ are proportional to $1 \otimes 8 \otimes 8$ tensors, i.e. $8 \otimes 8$ matrices, where $\bar{Q}$ is an octet operator. So the allowed mass dependence of the outer ring octet decay constants is similar to the allowed dependence of the octet masses. Thus we have

$$f(a\bar{b}) = F_0 + G(\delta m_u + \delta m_b)$$

$$+ H_0 \frac{1}{2}(\delta m_u^2 + \delta m^2_0 + \delta m_b^2) + H_1 (\delta m_u^2 + \delta m_b^2)$$

$$+ H_2 (\delta m_u - \delta m_b)^2 + \ldots.$$  

(5)

The SU(3) flavour symmetric breaking expansion has the simple property that for any flavour singlet quantity, which we generically denote by $X_S \equiv X_S(m_u, m_d, m_s)$ then

$$X_S(\bar{m} + \delta m_u, \bar{m} + \delta m_d, \bar{m} + \delta m_s) = X_S(\bar{m}, \bar{m}, \bar{m}) + O((\delta m_q)^2).$$  

(6)

This is already encoded in the above pseudoscalar SU(3) flavour symmetric breaking expansions, or more generally it can be shown, [11,12], that $X_S$ has a stationary point about the SU(3) flavour symmetric line.

Here we shall consider

$$X^2_{K} = \frac{1}{6}(M^2_{K^0} + M^2_{K^+} + M^2_{K^0} + M^2_{\pi^+} + M^2_{\pi^0} + M^2_{\pi^-}),$$

$$X_{f_0} = \frac{1}{6}(f_{K^0} + f_{K^+} + f_{K^+} + f_{\pi^+} + f_{\pi^0} + f_{K^-}).$$  

(7)

(The experimental value of $X_{\pi}$ is $\sim 410$ MeV, which sets the unitary range.) There are, of course, many other possibilities such as $S = N, \Lambda, \Sigma^*$, $\Delta, \rho, \eta_0, \eta_0, \omega_0, [11,12,14].$

As a further check, it can be shown that this property also holds using chiral perturbation theory. For example for mass degenerate $u$ and $d$ quark masses and assuming $\chi$ PT is valid in the region of the SU(3) flavour symmetric quark mass we find

$$X_{f_0} = f_0 \left[1 + \frac{8}{f_0^2}(3L_4 + L_5) - 3L(\bar{X}) + O((\delta \bar{X})^2)\right]^{5/2}$$

(8)

where the expansion parameter is given by $\delta \bar{X} = \bar{X} - \chi$, with $\bar{X} = \frac{1}{6}(2X_1 + X_3)$, $X_1 = B_0m_0$, $X_3 = B_0m_3$, $f_0$ is the pion decay constant in the chiral limit, $L_i$ are chiral constants and $L(\bar{X}) = \chi ((4\pi f_0)^2 \times \ln(\chi / \Lambda^2))^4$ is the chiral logarithm. In eq. (8), as expected, there is an absence of a linear term $\propto \delta \bar{X}$.

The unitary range is rather small so we introduce PQ or partially quenching (i.e. the valence quark masses can be different to the sea quark masses). This does not increase the number of expansion coefficients. Let us denote the valence quark masses by $\mu_q$ and the expansion parameter as $\delta \mu_q = \mu_q - \bar{m}$. Then we have

$$M^2(a\bar{b}) = 1 + \bar{G}(\delta \mu_a + \delta \mu_b)$$

$$- \left(\frac{9}{2} H_1 + H_2\right) (\delta m^2_a + \delta m^2_b + \delta m^2_s)$$

$$+ \bar{G}_1 (\delta \mu_a^2 + \delta \mu_b^2) + \bar{G}_2 (\delta \mu_a - \delta \mu_b)^2$$

$$+ \ldots.$$  

(9)

and

$$f(a\bar{b}) = 1 + \bar{G}(\delta \mu_a + \delta \mu_b)$$

$$- \left(\frac{9}{2} H_1 + H_2\right) (\delta m^2_a + \delta m^2_b + \delta m^2_s)$$

$$+ \bar{H}_1 (\delta \mu_a^2 + \delta \mu_b^2) + \bar{H}_2 (\delta \mu_a - \delta \mu_b)^2$$

$$+ \ldots.$$  

(10)
Fig. 2. LH panel: $X_0^2$, $X_2^2$, $X_3^2$, $X_4^2$, $X_5^2$ versus $M_s^2/X_5^2$ for $(\beta, \kappa_0) = (5.50, 0.120900)$ along the $m = \text{const.}$ line, together with constant fits. Open symbols have $M_s L \leq 4$, where $L$ is the spatial lattice size, and are not included in the fit. The vertical line is the physical point. RH panel: The same for $(\beta, \kappa_0) = (5.80, 0.122810)$.

Fig. 3. LH panel: $(2M_R^2 - M_2^2)/X_2^2$ versus $M_2^2/X_2^2$, $S = N, \rho, \omega_0$ for $(\beta, \kappa_0) = (5.50, 0.120900)$. Stars represent the physical points, the dashed line is the SU(3) flavour symmetric line. RH panel: The same for $(\beta, \kappa_0) = (5.50, 0.120950)$.

where in addition to the PQ generalisation we have also formed the ratios $M_s^2 = M_2^2/X_2^2$, $\bar{M}_s^2 = M_2^2/X_2^2$ ... and $f = f/X_1^2$, $G = G/F_0$, ... (see Appendix A for the NNLO expressions). This will later prove useful for the numerical results. We see that there are mixed sea/valence mass terms at NLO (and higher orders). The unitary limit is recovered by simply replacing $\delta q \to \delta m_q$.

3. The lattice

We use an $O(a)$ non-perturbatively improved clover action with tree level Symanzik glue and mildly stout smeared $2 + 1$ clover fermions, [14,15], for $\beta \equiv 10/g_0^2 = 5.40, 5.50, 5.65, 5.80$ (four lattice spacings). We set

$$\mu_q = \frac{1}{2} \left( \frac{K_0^\text{val}}{K_0^\text{val} - 1} \right),$$

(11)

giving

$$\delta \mu_q = \mu_q - \bar{m} = \frac{1}{2} \left( \frac{1}{K_0^\text{val}} - 1 \right).$$

(12)

A $\kappa$ value along the SU(3) symmetric line is denoted by $\kappa_0$, while $\kappa_0$ is the value in the chiral limit. Note that practically we do not have to determine $\kappa_0$, as it cancels in $\delta \mu_q$. (For simplicity we have set the lattice spacing to unity.)

We first investigate the constancy of $X_5$ in the unitary region. In Fig. 2 we show various choices for $X_5$. It is apparent that over a large range, starting from the SU(3) flavour symmetric line, reaching down and approaching the physical point, $X_5$ appears constant, with very little evidence of curvature. (Although not included in the fits, the open symbols have $M_s L \sim 3-4$ and also do not show curvature.) Presently our available pion masses reach down to $\sim 220$ MeV.

Based on this observation, we determine the path in the quark mass plane by considering $M_2^2/X_2^2$ against $(2M_R^2 - M_2^2)/X_2^2$. If there is little curvature then we expect that

$$\frac{2M_R^2 - M_2^2}{X_2^2} = 3 \frac{X_2^2}{X_2^2} - 2 \frac{M_2^2}{X_2^2}.$$  

(13)

holds for $S = N, \rho, \omega_0, \omega_0, \omega_0, \ldots$. In Fig. 3 we show this for $(\beta, \kappa_0) = (5.50, 0.120900), (5.50, 0.120950)$. We see that this is indeed the case. In addition $\kappa_0$ is adjusted so that the path goes through (or very close to) the physical value. For example we see that from the figure, $\beta = 5.50$, $\kappa_0 = 0.120950$ is very much closer to this path than $\kappa_0 = 0.120900$, [14].

The programme is thus first to determine $\kappa_0$ and then find the expansion coefficients. Then use\textsuperscript{1} isospin symmetric 'physical'

\textsuperscript{1} Masses are taken from FLAG3, [16].
masses $M_{u*, v*}$ to determine $\delta m_{u*}$ and $\delta m_{v*}$. PQ results can help for the first task. As the range of PQ quark masses that can then be used is much larger than the unitary range, then the numerical determination of the relevant expansion coefficients is improved. PQ results were generated about $\kappa_0$, a single sea background, so $\gamma_1$ was not relevant. Also some coefficients (those $\propto (\delta \mu_a - \delta \mu_b)^2$) often just contributed to noise, so were then ignored. In Fig. 4 we show $M_{u*}^2$ against $\delta \mu_a + \delta \mu_b$. From the SU(3) flavour breaking expansions the leading-order or LO expansions are just a function of $\delta \mu_a + \delta \mu_b$; at higher orders, NLO etc., this is not the case (see eq. (9)). We see that there is linear behaviour (coincidence of the PQ data with the linear piece) in the masses at least for $M_{u*}^2 \lesssim 3$ or $M_{u*} \lesssim 410 \text{MeV} \sim 700 \text{MeV}$. In Fig. 5 we show the corresponding results for $\tilde{f}$. Again we see similar results for $\tilde{f}$ as for $M^2$; while our fit is describing the data well, the deviations from linearity occur earlier.

Furthermore the use of PQ results allows for a possibly interesting method for fine tuning of $\kappa_0$ to be developed. If we slightly miss the starting point on the SU(3) flavour symmetric line, we can also tune $\kappa_0$ using PQ results so that we get the physical values of (say) $M_{v*}^2$, $X_{N*}$ and $M_{v*}$. This gives $\kappa_0, \delta \mu_{v*}, \delta \mu_{u*}$. The philosophy is that most change is in the masses compared to the sea quark mass, rather than sea quark mass. Note that then $2\delta \mu_{v*} + \delta \mu_{u*} \neq 0$ necessarily (while $2\delta m_{u*} + \delta m_{v*}$ always vanishes). For our $\kappa_0$ values used here, namely $(\beta, \kappa_0) = (5.40, 0.119930), (5.50, 0.120950), (5.65, 0.122005), (5.80, 0.122810), [14]$ (on $24^3 \times 48, 32^3 \times 64, 32^3 \times 64$ and $48^3 \times 96$ lattice volumes respectively) tests show this is a rather small correction and we shall use this as part of the systematic error, see Appendix C.

Of course the unitary range is much smaller, as can be seen from the horizontal lines in Fig. 4. In the LH panel of Fig. 6 we show this range as a function of $\delta m_l$ for $M_{v*}^2$, $M_{u*}^2$ and $M_{v*}^2$, together with the previously found fits. The expressions are given from eq. (9), setting $\delta \mu \rightarrow \delta m_q$ and then $a \rightarrow u, b \rightarrow d$ with $m_u = m_d \equiv m_{q*}$ for $M_{u*}^2$ etc. Here we clearly observe the typical ‘fan’ behaviour seen in the mass of other hadron mass multiplets [12]. As we have mass degeneracy at the symmetric point, the masses radiate out from this point to their physical values. For both $M^2$ and $\tilde{f}$ the LO completely dominates.

As can be seen from the LH panel of Fig. 6 when $M_{v*}$ takes its physical value, $M_{u*}^2$, this determines the physical value $\delta m_{u*}$. These are given in Table 1. Note that due to the constraint given in eq. (3) then $\delta m_{v*}^2 = -2\delta m_l^*$.

4. Decay constants

The renormalised and $O(a)$ improved axial current is given by

$$A_{\mu}^{ab; R} = Z_A A_{\mu}^{ab; \text{IM}}$$

with

$$A_{\mu}^{ab; \text{IM}} = \left(1 + \left[\tilde{b}_A m + \frac{1}{2} b_A (m_a + m_b)\right]\right) A_{\mu}^{ab},$$

$$A_{\mu}^{ab} = \tilde{A}_{\mu}^{ab} + c_A \tilde{\gamma}_\mu p_{ab},$$

and

$$A_{\mu}^{ab} = \tilde{A}_{\mu}^{ab} = \gamma_\mu \gamma_5 q_b, \quad p_{ab} = \gamma_\mu \gamma_5 q_b.$$

Using the axial current we first define matrix elements

$$\langle 0 | \hat{A}_4 | M \rangle = M f, \quad \langle 0 | \hat{A}_4^2 | M \rangle = M f^{(1)},$$

and for the renormalised pseudoscalar constants

$$f^R = Z_A \left(1 + c_A \frac{f^{(1)}}{f}\right) \left(1 + \left[\tilde{b}_A + b_A\right] m + \frac{1}{2} b_A (m_a + m_b)\right) f.$$

As indicated in Fig. 7, we note that $c_A$ is small (compared to unity) and that $f^{(1)}/f$ is constant and $\sim O(1)$ in the unitary region. So

$$\frac{f_K}{f_\pi} = 1.192(10)(13)$$

5. Results

5.1. $f_K/f_\pi$

As demonstrated in the RH panel of Fig. 6, we again expect LO behaviour for $SU(3)$ flavour symmetry breaking for $f$ to dominate in the unitary region. Using the coefficients for the $SU(3)$ flavour breaking expansion for $f^R$ as previously determined, and then extrapolating to the physical quark masses gives the results in Table 2. Finally using these results, we perform the final continuum extrapolation, using the lattice spacings given in [14], as shown in Fig. 8. (The fits have $\chi^2$/dof $\sim 3.3/2 \sim 1.6$.) For comparison, the FLAG3 values, [16], are shown as stars. (Note that although $f_K$ helps in determining the expansion coefficients, there is no further information to be found from the various extrapolated values.) Continuum values are also given in Table 2. Converting $f^R$ gives a result of

$$\frac{f_K}{f_\pi} = 1.192(10)(13)$$
At the physical point, using the FLAG3, [16], mass values gives 
\[ \Delta m^*/\delta m_i^* \] and hence using our determined value for \( f_{K^+}/f_{\pi^+} \), we find
\[ \delta_{SU(2)} = -0.0042(2)(2). \] (23)
Alternatively, this gives
\[ f_{K^+}^{\pi^+} = 1.190(10)(13). \]

6. Conclusions

We have extended our programme of tuning the strange and light quark masses to their physical values simultaneously by keeping the average quark mass constant from pseudoscalar meson masses to pseudoscalar decay constants. As for masses we find that the SU(3) flavour symmetry breaking expansion, or Gell-Mann–Okubo expansion, works well even at leading order.

Further developments to reduce error bars could include another finer lattice spacing, as the extrapolation lever arm in \( a^2 \) is rather large and presently contributes substantially to the errors, and QC results with sea quark masses not just at the symmetric point \( (m) \) but at other points on the \( m = \text{const. line} \).

Appendix A. Next-to-next-to leading order expansion

We give here the next-to-next-to leading order PQ expansion or NNLO PQ expansion for the octet pseudoscalars and decay constants, which generalise the results of eqs. (4), (9) and eqs. (5), (10). For the pseudoscalar mesons we have
\[ M^2(ab) = M_0^2 + \alpha(\delta m_a + \delta m_b) \]
\[ + \beta_1(\delta m_a^2 + \delta m_b^2 + \delta m_i^2) + \beta_2(\delta m_a^2 + \delta m_b^2 + \delta m_i^2) \]
\[ + \gamma_1(\delta m_a + \delta m_b)(\delta m_a^2 + \delta m_b^2 + \delta m_i^2) + \gamma_2(\delta m_a + \delta m_b)^2, \]
and
\[ \bar{M}^2(ab) = 1 + \bar{\alpha}(\delta m_a + \delta m_b) \]
\[ - \left( \frac{2}{3} \bar{\beta}_1 + \bar{\beta}_2 \right)(\delta m_a^2 + \delta m_b^2 + \delta m_i^2) \]
\[ + \bar{\beta}_1(\delta m_a^2 + \delta m_b^2) + \bar{\beta}_2(\delta m_a - \delta m_b)^2 \]
\[ + (2\gamma_2 - 6\gamma_3)\delta m_a \delta m_b \delta m_i \]
\[ + \bar{\gamma}_1(\delta m_a + \delta m_b)(\delta m_a^2 + \delta m_b^2 + \delta m_i^2). \]
\[+ \tilde{\gamma}_2 (\delta \mu_a + \delta \mu_b)^3 + \tilde{\gamma}_3 (\delta \mu_a + \delta \mu_b)(\delta \mu_a - \delta \mu_b)^2, \]  
(25)

where \( \tilde{\mu}(a \tilde{b}) = M^2(a \tilde{b})/X_\pi^2 \) and for an expansion coefficient \( \tilde{\alpha} = \alpha/M_0, \tilde{\beta} = \beta_i/M_0, i = 1, 2, \) and \( \tilde{\gamma}_1 = \gamma_i/M_0, i = 1, 2, 3 \) and we have then redefined \( \tilde{\gamma}_1 \) by \( \tilde{\gamma}_1 = \gamma_i \tilde{\beta}_1^2 + \tilde{\beta}_1 \tilde{\beta}_2 \rightarrow \tilde{\gamma}_1. \)

The SU(3) flavour breaking expansion is identical for the decay constants, we just replace \( M_0 \rightarrow F_0, \alpha \rightarrow G, \tilde{\beta}_i \rightarrow H_i, \gamma_i \rightarrow I_i \) in eq. (24) and \( \tilde{\alpha} \rightarrow \tilde{G}, \tilde{\beta}_i \rightarrow \tilde{H}_i, \tilde{\gamma}_i \rightarrow \tilde{I}_i \) in eq. (25).

Appendix B. Correlation functions

On the lattice we extract the pseudoscalar decay constant from two-point correlation functions. For large times we expect that

\[ C_{A_P}(t) = \frac{1}{V_S} \sum_X \sum_Y A_X(\tilde{x}, t) \sum_Y P(\tilde{y}, t) \]

\[ = \frac{1}{2M} \left( \langle 0 \mid \hat{A}_4 | M \rangle \langle 0 \mid \hat{P} | M \rangle^* e^{-Mt} + \langle 0 \mid \hat{P}^\dagger \hat{A}_4 | M \rangle \langle 0 \mid \hat{P} | M \rangle e^{-M(T-t)} \right) \]

\[ = -A_{Ap} \left[ e^{-Mt} - e^{-M(T-t)} \right], \]

and

\[ C_{PP}(t) = \frac{1}{V_S} \sum_X \sum_Y P(\tilde{x}, t) \sum_Y P(\tilde{y}, t) \]

\[ = \frac{1}{2M} \left( \langle 0 \mid \hat{P} | M \rangle \langle 0 \mid \hat{P} | M \rangle^* e^{-Mt} + \langle 0 \mid \hat{P}^\dagger | M \rangle \langle 0 \mid \hat{P} | M \rangle e^{-M(T-t)} \right) \]

\[ = A_{PP} \left[ e^{-Mt} + e^{-M(T-t)} \right], \]

where \( A_{Ap} \) and \( P_{PP} \) are given in eq. (16). We have suppressed the quark indices, so the equations with appropriate modification are valid for both the pion and kaon. \( V_S \) is the spatial volume and \( T \) is the temporal extent of the lattice. To increase the overlap of the operator with the state (where possible) the pseudoscalar operator has been smeared using Jacobi smearing, and denoted here with a superscript, \( S \) for Smear. We now set

\[ \langle 0 | \hat{A}_4 | M \rangle = M f \]

\[ \langle 0 | \hat{P} | M \rangle = - \sinh M \langle 0 | \hat{P} | M \rangle = M f^{(1)}, \]

(28)

where \( f, f^{(1)} \) are real and positive. By computing \( C_{A_P} \) and \( C_{PP} \) we find for the matrix element of \( \hat{A}_4 \),

\[ Mf = \sqrt{2M} \times \frac{A_{Ap} \times \sqrt{A_{PP}}}{A_{PP} \times \sqrt{A_{Ap}}} \]

(29)

and for the matrix element of \( \hat{P} \) we obtain from the ratio of the \( C_{PP} \) and \( C_{Ap} \) correlation functions

\[ \frac{f^{(1)}}{f} = \text{sinh} M \times \frac{A_{PP} \times \sqrt{A_{Ap}}}{A_{Ap} \times \sqrt{A_{PP}}} \]

(30)

Some further details and formulae for other decay constants are given in [20,21].

Appendix C. Systematic errors

We now consider in this Appendix possible sources of systematic errors.

Uncertainty in \( b_A \)

Presently the improvement coefficient \( b_A \) is only known perturbatively to leading order. We have estimated the uncertainty here by repeating the analysis with \( b_A = 0 \) and \( b_A = 2 \). This leads to a systematic error on \( f_K/f_\pi \) of \( \sim 0.008 \).

SU(3) flavour breaking expansion

We first note that for the unitary range as illustrated in Fig. 6, the ‘ruler test’ indicates there is very little curvature. This shows that the SU(3) flavour breaking expansion is highly convergent. (Each order in the expansion is multiplied by a further power of \( |\delta m_i| \sim 0.01 \).) This is also indicated in Fig. 2, where our lowest pion mass there is \( \sim 220 \text{ MeV} \). Such expansions are very good compared to most approaches available to QCD. Comparing the LO (linear) approximation with the non-linear fit gives an estimation of the systematic error. The comparison yields the estimate to be \( \sim 0.004 \) for \( f_K/f_\pi \).

Finite lattice volume

All the results used in the analysis here have \( M_f L \gtrsim 4 \). We also have generated some PQ data for \( (\beta, k_0) = (5.80, 0.122810) \) on a smaller lattice volume \( -32^4 \times 64 \). (This still has \( M_f L > 4 \).) Performing the analysis leads to small changes in \( f \). Making a continuum extrapolation (which is most sensitive to just the \( \beta = 5.80 \) point) and comparing the result with that of eq. (20) results in a systematic error of \( \sim 0.005 \).

Path to physical point

As discussed in section 3, we can further tune \( k_0 \) using PQ results to get the physical values \( M_\pi^*, X_N^* \) and \( M_K^* \) correct. To give \( k_0, \delta m_1^*, \delta m_2^* \), setting \( \delta \Pi^* = (2\delta \mu_1^* + \delta \mu_2^*)/3 \) then at LO this average is given by

\[ \delta \Pi^* = \frac{1}{2\alpha} \left( \frac{X^2}{X_N^2} \right)^{-1} \]

(31)

(while \( 2\delta m_1^* + \delta m_2^* \) is always \( 0 \)). This gives for example for \( \beta = 5.80, \delta \Pi^* \sim -0.0001 \). Changing \( \delta m_1^* \) (or \( \delta m_2^* \)) by this and making a continuum extrapolation (which is again most sensitive to this point) and comparing the result with that of eq. (20) results in a systematic error of \( \sim 0.009 \).

Total systematic error

Including all these systematic errors in quadrature give a total systematic estimate in \( f_K/f_\pi \) of \( \sim 0.013 \).
