## Introduction

The need for **reproducible research** is a topic of intense discussion in the neurosciences. In the context of **data analysis**, we develop the Electrophysiology Analysis Toolkit (**Elephant**, [1]) as a central resource to provide tested and validated reference implementations of common analysis methods for activity data. However, reproducibility also requires such tools to be embedded in **collaborative, holistic workflows** [2] providing **clear, traceable** analysis steps from data acquisition to publication.

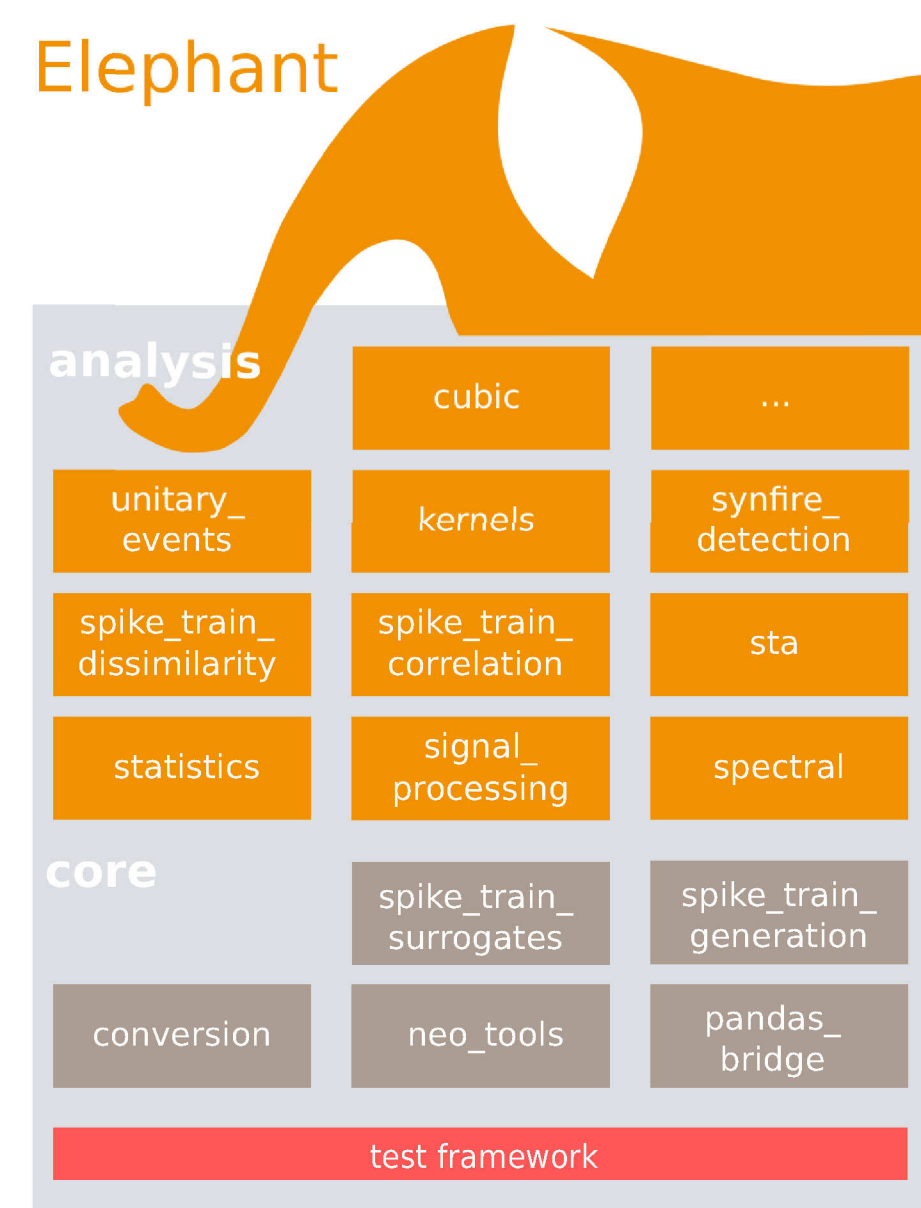

Here, we showcase how **Elephant** is integrated into an analysis workflow running on the the **Collaboratory**, reproducing work in [3]. The workflow consists of complementary open-source tools and services [4] for: metadata management (**odML** and **odMLtables**, [5,6,7]), data query (HBP **Knowledgegraph**, [8]), data versioning (**gin**, [9]), data storage (**nix**, [10]), data handling (**Neo**, [11]). Finally, we outline how these building blocks, combined with generic tools, can be assembled into formalized workflows to support reproducible research, e.g. the validation of network simulations with **NetworkUnit**.

## Analysis using Elephant

**Elephant** is a community-centered, open-source software package that provides components for the analysis of multi-scale electrophysiological data (e.g., spike trains, local field potentials) from experiments and neuronal simulations, focusing on:

- methods for the analysis of parallel recordings
- correlative features of brain dynamics
- bridging different scales of observation

## Summary

### The presented analysis workflow...

- ... **combines** several public, community-centered software tools to achieve a reproducible analysis.
- ... is re-usable and suitable for **collaborative work** between laboratories by use of the HBP **Collaboratory**.
- ... provides a comprehensible data flow across scales **independent of the data format** using the **Neo** library.
- ... leads the way towards the implementation of **future analysis workflows** based on the **Elephant** library.

## Multi-scale analysis workflow on the Collaboratory

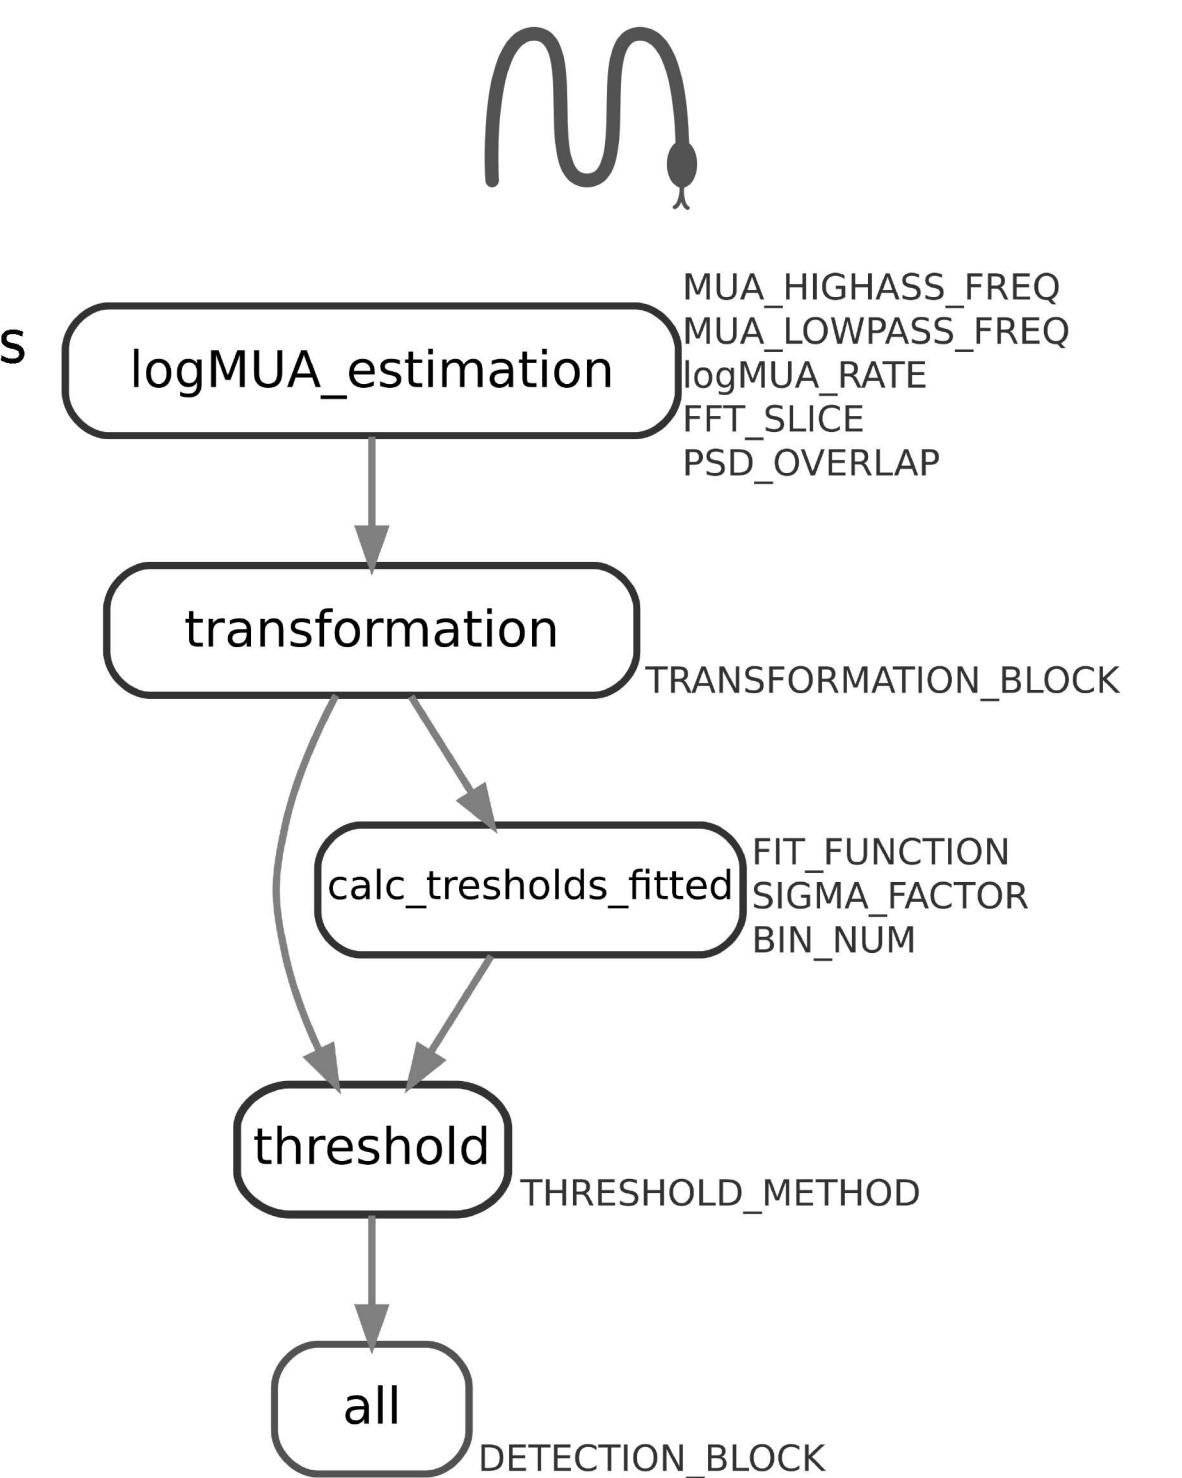

The **Collaboratory** infrastructure of the Human Brain Project hosts the overall workflow of the project, required tools, central data management, data search, HPC access, and the ability for interactive work. The implementation employs a variety of existing tools to describe the workflow in a **generalized** and **reusable** form. It is structured as a hierarchical arrangement of **modular** elements. The top level is a **pipeline**, which is composed of sequential **stages**. Each **stage** is a collection of modular analysis/processing **blocks**.

- The execution instructions of blocks and stages are defined with **Snakemake**.
- Parameter settings and the selection of **blocks** is separated in config files.
- The interfaces between **stages/blocks** are standardized (**Neo**, **pandas**).
- The **blocks** use standard implementations of algorithms (e.g from **Elephant**).
- **Fairgraph** enables fetching data and storing (intermediate) analysis results as well as analysis activity (provenance) with the **KnowledgeGraph**.

→ **reproducible & comparable analysis/validation/benchmarking**

```
rule frequency_filter:
    input:
        data = input_file,
        script = 'scripts/frequency_filter.py',
        config = 'config.yaml'
    output:
        data = os.path.join(output_path, 'frequency_filter.nix'),
    shell:
        """
        python {input.script} --data "{input.data}" \
                               --output "{output.data}" \
                               --highpass_freq {config['HIGHPASS_FREQ']} \
                               --lowpass_freq {config['LOWPASS_FREQ']} \
                               --order {config['FILTER_ORDER']} \
                               --filter_function {config['FILTER_FUNCTION']}
        """
```

## Validation with NetworkUnit

- **Validation** is the process of establishing confidence in a model by quantitatively testing whether its prediction accuracy is within an acceptable agreement to its system of interest.
- **Network-level validation** evaluates the model simulation on the level of the network activity as opposed to the complementary approach of validating on a single-cell level.
- **Model-to-model validation** compares models (or their implementations) for consistency, cross-validation, simulator evaluation, or quantification of model developments. [12]

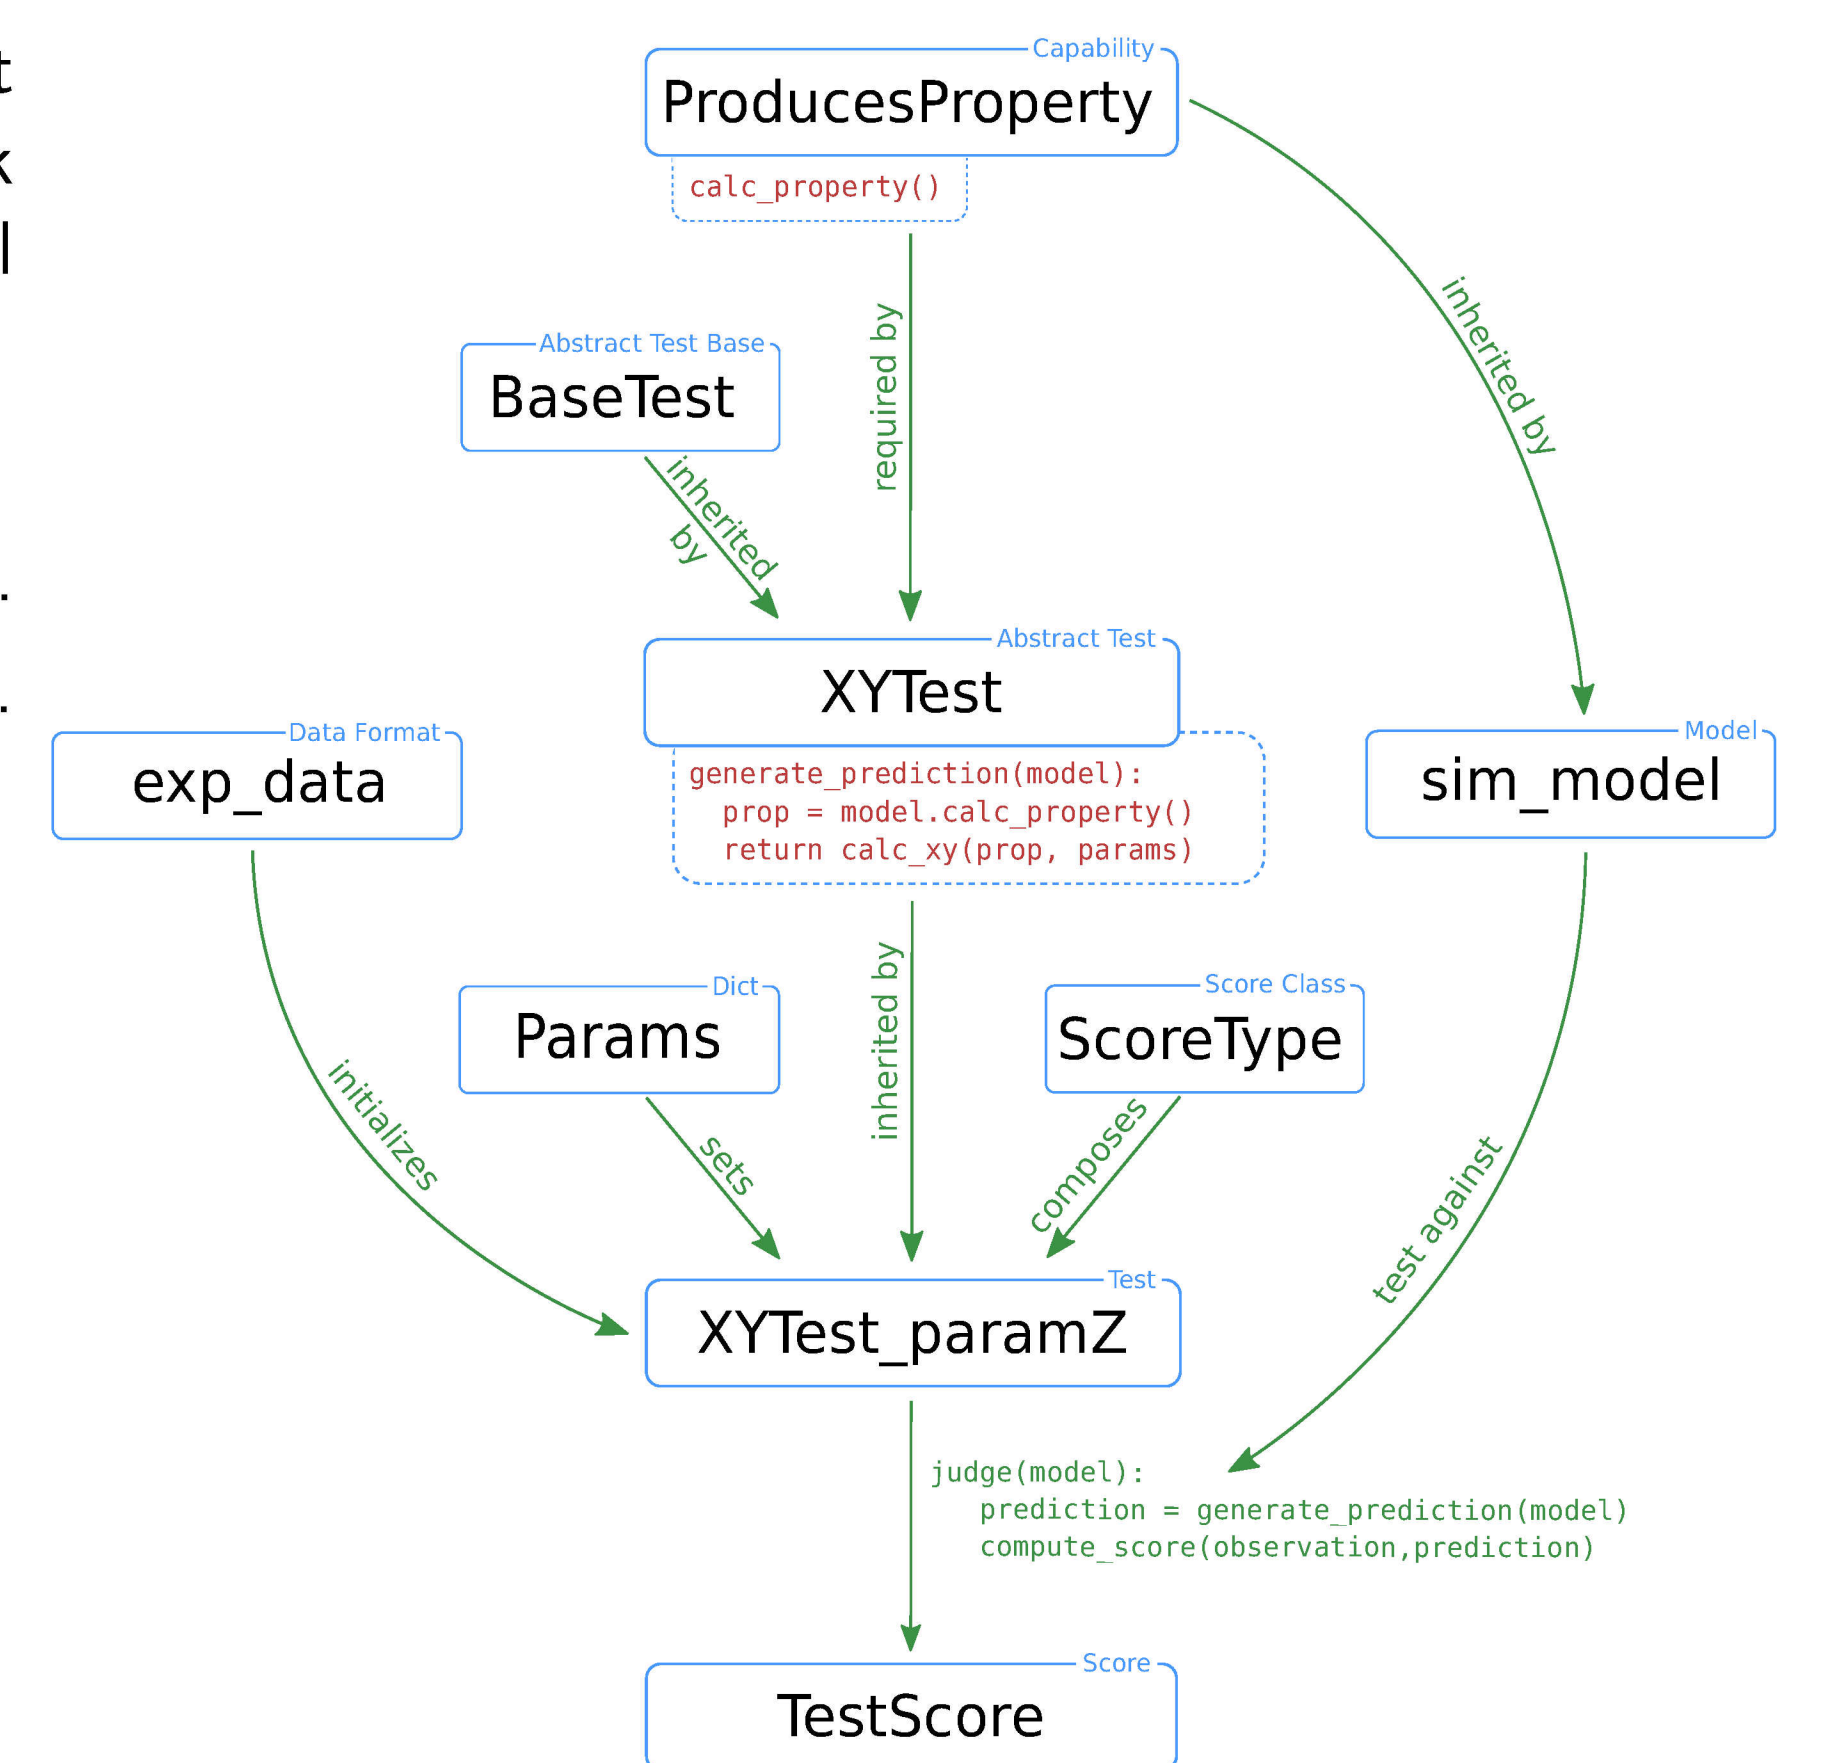

The Python module **NetworkUnit** [13] is based on SciUnit [14] and **Elephant**, and provides a formalized framework along with a battery of standardized tests for network-level validation.

- Models are matched to appropriate tests via 'capabilities'.
- New tests can be easily derived from a range of base tests.
- Tests can be adapted to also compare multiple models.
- Test scores are annotated with their provenance.

**Standardization → Reproducibility**

**Modularization → Versatility**

**Formalization → Understandability**
