ABSTRACT: The nature of the three narrow hidden-charm pentaquark P_c states, i.e., $P_c(4312)$, $P_c(4440)$ and $P_c(4457)$, is under intense discussion since their discovery from the updated analysis of the process $\Lambda_b^0 \rightarrow J/\psi p K^-$ by LHCb. In this work we extend our previous coupled-channel approach [Phys. Rev. Lett. **124**, 072001 (2020)], in which the P_c states are treated as $\Sigma_c^{(*)} \bar{D}^{(*)}$ molecules, by including the $\Lambda_c \bar{D}^{(*)}$ and $\eta_c p$ as explicit inelastic channels in addition to the $J/\psi p$, as required by unitarity and heavy quark spin symmetry (HQSS), respectively. Since inelastic parameters are very badly constrained by the current data, three calculation schemes are considered: (a) scheme I with pure contact interactions between the elastic, i.e., $\Sigma_c^{(*)} \bar{D}^{(*)}$, and inelastic channels and without the $\Lambda_c \bar{D}^{(*)}$ interactions, (b) scheme II, where the one-pion exchange (OPE) is added to scheme I, and (c) scheme III, where the $\Lambda_c \bar{D}^{(*)}$ interactions are included in addition. It is shown that to obtain cutoff independent results, OPE in the multichannel system is to be supplemented with S -wave-to- D -wave mixing contact terms. As a result, in line with our previous analysis, we demonstrate that the experimental data for the $J/\psi p$ invariant mass distribution are consistent with the interpretation of the $P_c(4312)$ and $P_c(4440)/P_c(4457)$ as $\Sigma_c \bar{D}$ and $\Sigma_c \bar{D}^*$ hadronic molecules, respectively, and that the data show clear evidence for a new narrow state, $P_c(4380)$, identified as a $\Sigma_c^* \bar{D}$ molecule, which should exist as a consequence of HQSS. While two statistically equally good solutions are found in scheme I, only one of these solutions with the quantum numbers of the $P_c(4440)$ and $P_c(4457)$ being $J^P = 3/2^-$ and $1/2^-$, respectively, survives the requirement of regulator independence once the OPE is included. Moreover, we predict the line shapes in the elastic and inelastic channels and demonstrate that those related to the $P_c(4440)$ and the $P_c(4457)$ in the $\Sigma_c^{(*)} \bar{D}$ and $\eta_c p$ mass distributions from $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D} K^-$ and $\Lambda_b^0 \rightarrow \eta_c p K^-$ will shed light on the quantum numbers of those states, once the data are available. We also investigate possible pentaquark signals in the $\Lambda_c \bar{D}^{(*)}$ final states.

1 Introduction

A quantitative understanding of hadron spectra plays a key role in our understanding of the strong interaction as well as its fundamental underlying theory, i.e., quantum chromodynamics (QCD). For a long time, hadrons were believed to be composed of either a pair of quark and antiquark ($q\bar{q}$) or three quarks (qqq) according to the conventional quark model. However, the confinement property of QCD in principle allows for the existence of any color neutral object, such as multiquarks, hybrids, glueballs, hadronic molecules and so on, which are usually called exotic states. Up to now, a tremendous number of candidates for having an exotic structure has been observed [1–13]. Among them the observation of the $P_c(4380)$

and $P_c(4450)$ [14], as the first observation of pentaquarks, in 2015 builds a landmark. They decay strongly into $J/\psi p$ and thus contain at least five quarks, $c\bar{c}uud$. The existence of these two pentaquark states is consistent with a model-independent reanalysis of the same data sample [15] and a full amplitude analysis of the $\Lambda_b^0 \rightarrow J/\psi p \pi^-$ decay [16]. A later analysis based on an order-of-magnitude larger data sample, i.e., the combined data set collected in Run 1 and Run 2 by the LHCb Collaboration, shows that the $P_c(4450)$ structure consists of two narrow overlapping peaks, i.e., $P_c(4440)$ and $P_c(4457)$, and a third narrow peak $P_c(4312)$ emerges [17]. However, the verification of the broad $P_c(4380)$ reported in 2015 awaits a complete amplitude analysis. Numerous theoretical interpretations of the nature of the pentaquarks followed these discoveries, including hadronic molecules [18–48], compact pentaquarks states [43, 49–54], hadro-charmonia [55–57], and cusp effects [43].

The proximity of the $\Sigma_c \bar{D}^{(*)}$ thresholds to these narrow pentaquark structures suggests that the corresponding two-hadron states play an important role in the dynamics of the pentaquarks, hinting at an interpretation of their structure as hadronic molecules. In the most common hadronic molecular picture, the $P_c(4312)$ is an S -wave $\Sigma_c \bar{D}$ bound state, while the $P_c(4440)$ and $P_c(4457)$ are bound states of $\Sigma_c \bar{D}^*$ with different spin structures, see e.g., refs. [21, 26, 32, 40, 46]. The origin of the peak from the $P_c(4312)$ is attributed to a virtual state of $\Sigma_c \bar{D}$ in ref. [58] based on an amplitude analysis,¹ which only fits to data around the $\Sigma_c \bar{D}$ threshold. In ref. [43], final state interactions are constructed based on a K -matrix including the channels $J/\psi p$ - $\Sigma_c \bar{D}$ - $\Sigma_c \bar{D}^*$. The analysis suggests that the $P_c(4312)$ is a $\Sigma_c \bar{D}$ molecule, while the $P_c(4440)$ could be a compact pentaquark state, and the $P_c(4457)$ could be caused by the cusp effect.²

While the proximity of the narrow P_c peaks to the $\Sigma_c \bar{D}^{(*)}$ make the molecular interpretation very compelling, at least some peaking structures in the $J/\psi p$ mass distributions can be also generated by the triangle singularities [11, 17, 61–64]. A triangle singularity arises when all intermediate particles in a triangle loop are (nearly) on-mass-shell. Therefore its location is quite sensitive to the masses and widths of the involved particles [11]. The potential triangle singularities were discussed in ref. [17] for the three P_c structures. Considering the realistic widths of the exchanged resonances, the $P_c(4312)$ and $P_c(4440)$ structures are unlikely to be caused by triangle singularities. However, the $P_c(4457)$ structure could in principle be produced by a triangle diagram with $D_{s1}^*(2860)$, $\Lambda_c(2595)$ and \bar{D}^{*0} in the intermediate state. It is worth noticing that even if $P_c(4312)$ and $P_c(4440)$ are not generated by triangle singularities, this does not necessarily mean that triangle diagrams play no role in producing these states. In the present work, however, we assume a pointlike production mechanism of the P_c states and focus on a coupled-channel approach for the final-state interactions of the $\Sigma^{(*)} \bar{D}^{(*)}$ as well as the inelastic channels. This means that in this work the possible effects of the triangle singularities on the pentaquark production are absorbed into the parameters of the production vertex. A study of the dynamical role of triangle diagrams will be the focus of future studies, once more data become available.

¹As a consequence of being a near-threshold virtual state, the peak for the $P_c(4312)$ should behave as a sharp threshold cusp. It is due to the convolution with the energy resolution that the peak shown in ref. [58] is smooth.

²A strong threshold cusp effect normally requires the existence of a near-threshold pole in an unphysical Riemann sheet (RS) [11, 59, 60].

To make further progress it is necessary to systematically investigate the implications of the symmetries of QCD, here, most importantly, heavy quark spin symmetry (HQSS). In simple terms, under the assumption that the observed pentaquarks are of molecular nature, the symmetry allows one to predict additional states, the so-called spin partners. To be concrete, HQSS predicts seven P_c states which are classified into two heavy quark spin multiplets. Three of these seven correspond to the ones reported by LHCb [21, 40, 65, 66]: while the $P_c(4312)$ is unambiguously assigned to the $J^P = \frac{1}{2}^- \Sigma_c \bar{D}$ bound state, there are two possible spin structures for the $P_c(4440)$ and $P_c(4457)$ identified as the $\Sigma_c \bar{D}^*$ bound states, namely $J^P = \frac{1}{2}^-$ and $J^P = \frac{3}{2}^-$ [21, 23, 40], and their spin assignment is not uniquely fixed by HQSS alone [19, 22, 35, 40, 67]. In ref. [40], the $J/\psi p$ invariant mass distribution of the $\Lambda_b^0 \rightarrow J/\psi p K^-$ process was described in the molecular scenario. In particular, the $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels (in what follows called elastic channels, since their thresholds are close to the P_c states) and the $J/\psi p$ channel (inelastic channel) were included dynamically. The interactions between elastic channels were constrained by HQSS, which guarantees that there are only two momentum-independent contact potentials, reflecting that the number of independent multiplets is two. The effect from additional inelastic channels, such as the $\Lambda_c \bar{D}^{(*)}$ and $\eta_c p$ channels and so on, was absorbed into additional imaginary parts of the two contact potentials in the spirit of an optical potential. For the case of only contact potentials, two different solutions, corresponding to scenarios *A* and *B* in ref. [21], were found describing the data almost equally well. Each of them gives seven poles in the $\Sigma_c^{(*)} \bar{D}^{(*)}$ scattering amplitudes, however, with different pole locations. Meanwhile, as soon as the one-pion-exchange (OPE) potentials was included, only one solution was found which suggests that $P_c(4440)$ and $P_c(4457)$ couple dominantly to the $\Sigma_c \bar{D}^*$ with quantum numbers $J^P = \frac{3}{2}^-$ and $\frac{1}{2}^-$, respectively [40]. In both fits, the $P_c(4312)$ couples dominantly to the $\Sigma_c \bar{D}$ channel with $J^P = \frac{1}{2}^-$. In addition, evidence for an additional narrow state, also called for by HQSS, around 4.38 GeV was found in the data with $J^P = \frac{3}{2}^-$, which couples dominantly to the $\Sigma_c^* \bar{D}$ (see also refs. [25, 46]).

The mentioned imaginary parts of the contact terms violate unitarity. In this work we overcome this shortcoming by including explicitly the supposedly most prominent additional inelastic channels, namely, $\Lambda_c \bar{D}^{(*)}$ and $\eta_c p$ making the mentioned imaginary parts of the contact terms obsolete. The inclusion of the $\eta_c p$ channel explicitly is also necessary from HQSS, since the η_c and J/ψ are in the same HQSS multiplet. While the interactions of $\eta_c p$ and $J/\psi p$ with the elastic channels are of a short-range character, $\Lambda_c \bar{D}^{(*)}$ can also interact with $\Sigma_c^{(*)} \bar{D}^{(*)}$ via one-pion exchange. Thus, when the $\Lambda_c \bar{D}$ and $\Lambda_c \bar{D}^*$ channels are included explicitly, three-body effects from the $\Lambda_c \bar{D} \pi$ intermediate states have to be taken into account in both the $\Sigma_c^* \bar{D}^{(*)} \rightarrow \Lambda_c \bar{D}^{(*)}$ transition potentials and the $\Sigma_c^{(*)}$ self-energy [68] (for recent discussions on the subject see refs. [69, 70]). The $\Sigma_c^{(*)}$ width may have a sizable effect on the widths of the $\Sigma_c^{(*)} \bar{D}^{(*)}$ molecular states. This is especially important for those states that have a prominent $\Sigma_c^* \bar{D}^{(*)}$ component, since the Σ_c^* width, which is around 15 MeV [71], is of the same order as the widths of the pentaquarks. Among them, the narrow $P_c(4380)$ attracts special interest, since its confirmation would provide strong support for the molecular picture. Equipped with the mentioned extensions of the approach, in this work we are also in a position to investigate the invariant mass distribu-

tions in all the elastic and inelastic channels to understand what can be learned from the corresponding data, once they exist.

Before we proceed, a remark on the treatment of the OPE in effective field theories (EFTs) is in order. As discussed in ref. [72], the OPE potential is well defined in the sense of an EFT only in connection with contact operators, the dependence of which on the regulator is dictated by the renormalisation group. Thus, the question if the OPE alone provides sufficient binding to produce shallow bound states cannot be addressed from an EFT perspective. In addition, to preserve HQSS in a coupled-channel problem with OPE, all relevant channels need to be coupled with each other: the omission of the off-diagonal transitions between some particle channels or partial waves leads to a strong violation of HQSS [73]. To the best of our knowledge, the aforementioned conditions are not satisfied in the previous studies available in the literature, where the OPE was included, see, e.g., refs. [28, 34, 35, 37, 39, 67, 74–76]. However, these conditions are crucial to unearth the true impact of the OPE on the formation of the molecular states. Thus, in what follows, we aim at the construction of a field theoretically consistent formalism, where the renormalisation of the OPE is carried out in a way consistent with the requirements of renormalisation group invariance and HQSS.

It was recently noticed in studies of the $X(3872)$ and Z_b systems [73, 77] that, in line with what is well-known for the nucleon-nucleon interaction [78], the most prominent contribution from the OPE originates from the tensor force inducing significant S - D transitions. However, the situation in the heavy quark sector is more complicated than in nuclear EFT because transitions between the different channels connected by HQSS, can be separated by more than 100 MeV due to the D^* - D and Σ_c^* - Σ_c mass differences. The resulting sizable momentum scales enhance further the role of the S - D transitions. The analysis of the line shapes relevant for the $Z_b(10610)/Z_b(10650)$ and their spin partners [79, 80] showed that, to remove the strong regulator dependence caused by the high-momentum contribution from the S - D OPE transitions, the formally next-to-leading-order (NLO) contact term for the S - D transitions is required to be promoted to leading order (LO). Meanwhile, the NLO S - S contact terms are numerically marginal, consistent with the expectations. In line with the observations of refs. [79, 80], if we omit the S - D counter terms in the pentaquark system, we also observe a strong dependence on the regulator, as soon as the OPE is included in the $\Sigma_c^{(*)}\bar{D}^{(*)} \rightarrow \Sigma_c^{(*)}\bar{D}^{(*)}$ and $\Sigma_c^{(*)}\bar{D}^{(*)} \rightarrow \Lambda_c\bar{D}^{(*)}$ transition potentials. Following refs. [79, 80], one expects that introducing the S - D contact terms allows us to obtain regulator-independent results and, at the same time, to arrive at a satisfying description of the data. However, only one of the two statistically almost equivalent solutions present in the pionless formulation survives the strict requirements of renormalizability upon the inclusion of the OPE together with the S - D term. The second solution still shows a strong regulator dependence, which can not be cured by the S - D counter terms only, and, accordingly, is treated here as unreliable. The cutoff independent solution suggests that the quantum numbers of the $P_c(4440)$ and $P_c(4457)$ should be $J^P = \frac{3}{2}^-$ and $\frac{1}{2}^-$, respectively, in line with ref. [40]. Moreover, we predict the possible line shapes of the $\Sigma_c^{(*)}\bar{D}^{(*)}$ and $\eta_c p$ mass distributions from $\Lambda_b^0 \rightarrow \Sigma_c^{(*)}\bar{D}^{(*)}K^-$ and $\Lambda_b^0 \rightarrow \eta_c p K^-$, which can be used to test the hadronic molecular nature of the P_c states, determine their quantum numbers experimentally and verify the existence of the missing P_c states.

The paper is organized as follows. In section 2 we derive the effective interaction potentials for the dynamical channels and parametrize the relevant weak production vertices. In particular, in subsection 2.1, we discuss the purely contact potentials in the basis of heavy-light spin degrees of freedom. In subsections 2.2 and 2.3, we derive the OPE and the S - D contact terms from the effective Lagrangian. The relativistic Lippmann-Schwinger equations (LSEs) with the dynamical width of $\Sigma_c^{(*)}$ are given in section 3. The fitting schemes to the $J/\psi p$ mass distributions are presented in section 4. Section 4.1 is devoted to a study, in which only contact potentials are considered. The OPE potentials are included in section 4.2 and the explicit inclusion of the $\Lambda_c \bar{D}^{(*)}$ is investigated in section 4.3. The pole positions and their effective couplings are also explicitly presented for schemes I and II. In addition, we also predict the line shapes for the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\eta_c p$ (and $\Lambda_c \bar{D}^{(*)}$ for scheme III) mass distributions in the $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K^-$ and $\Lambda_b^0 \rightarrow \eta_c p K^-$ (and $\Lambda_b^0 \rightarrow \Lambda_c \bar{D}^{(*)} K^-$) processes. We summarize in section 5.

2 Effective potentials

In order to fully exploit the implications of HQSS and to study the role of the $\Lambda_c \bar{D}^{(*)}$ channels and the effect of the $\Sigma_c^{(*)}$ width stemming from the decay $\Sigma_c^{(*)} \rightarrow \Lambda_c \pi$, we extend the framework of ref. [40] to dynamically include the $\Lambda_c \bar{D}^{(*)}$ and $\eta_c p$ channels in addition to the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $J/\psi p$ channels. The effective transition potentials for those channels entering the LSEs contain short-range contact terms as well as OPE. In this section, both the contact and OPE potentials are presented employing the constraints from HQSS.

2.1 Contact potentials

The short-ranged contact potentials can be derived either from the effective Lagrangians or from the decomposition of the spin structures of the charm-anticharm and light degrees of freedom in the heavy-quark limit following, e.g., ref. [81]. As the later one is more intuitive and easier to be applied to the bare production amplitudes, we extract the LO contact potentials and the bare production amplitudes based on the heavy-light spin structures. Afterwards, we also show the construction based on the Lagrangian method — while it provides identical results it is easier extendable to higher orders.

Along this line, we expand the two-particle basis in terms of heavy-light spin structure $|s_Q \otimes j_\ell\rangle$, with s_Q and j_ℓ representing the total spin of the heavy quarks and the total angular momentum of light degrees of freedom, respectively. In the heavy-light spin structure basis, the $\Sigma_c^{(*)}$ and $\bar{D}^{(*)}$ are $|\frac{1}{2} \otimes 1\rangle$ and $|\frac{1}{2} \otimes \frac{1}{2}\rangle$ spin multiplets, respectively, while the Λ_c^+ corresponds to a $|\frac{1}{2} \otimes 0\rangle$ singlet. The higher partial-wave amplitudes for the orbital angular momentum ℓ are suppressed by a factor $(p/\Lambda)^{2\ell}$, where p is the center-of-mass (c.m.) frame three-momentum of the system and Λ denotes some typical hard scale commonly assumed to be of the order of 1 GeV. Accordingly, the short-ranged $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\Lambda_c \bar{D}^{(*)}$ potentials should be dominated by S waves, although, given the large range of momenta involved in the study, effects of the S - D mixing may also become important, as discussed below. The

S -wave $\Sigma_c^{(*)}\bar{D}^{(*)}$ and $\Lambda_c\bar{D}^{(*)}$ systems can be cast in terms of $|s_Q \otimes j_\ell\rangle$ as [32, 40, 65]

$$\begin{pmatrix} |\Sigma_c\bar{D}\rangle \\ |\Sigma_c\bar{D}^*\rangle \\ |\Sigma_c^*\bar{D}^*\rangle \\ |\Lambda_c\bar{D}\rangle \\ |\Lambda_c\bar{D}^*\rangle \end{pmatrix}_{\frac{1}{2}} = \begin{pmatrix} \frac{1}{2} & \frac{1}{2\sqrt{3}} & \frac{\sqrt{2}}{3} & 0 & 0 \\ \frac{1}{2\sqrt{3}} & \frac{5}{6} & -\frac{\sqrt{2}}{3} & 0 & 0 \\ \sqrt{\frac{2}{3}} & -\frac{\sqrt{2}}{3} & -\frac{1}{3} & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ 0 & 0 & 0 & \frac{\sqrt{3}}{2} & \frac{1}{2} \end{pmatrix} \begin{pmatrix} |0 \otimes \frac{1}{2}\rangle \\ |1 \otimes \frac{1}{2}\rangle \\ |1 \otimes \frac{3}{2}\rangle \\ |0 \otimes \frac{1}{2}\rangle' \\ |1 \otimes \frac{1}{2}\rangle' \end{pmatrix}, \quad (2.1)$$

$$\begin{pmatrix} |\Sigma_c\bar{D}^*\rangle \\ |\Sigma_c^*\bar{D}\rangle \\ |\Sigma_c^*\bar{D}^*\rangle \\ |\Lambda_c\bar{D}^*\rangle \end{pmatrix}_{\frac{3}{2}} = \begin{pmatrix} \frac{1}{\sqrt{3}} & -\frac{1}{3} & \frac{\sqrt{5}}{3} & 0 \\ -\frac{1}{2} & \frac{1}{\sqrt{3}} & \frac{1}{2}\sqrt{\frac{5}{3}} & 0 \\ \frac{1}{2}\sqrt{\frac{5}{3}} & \frac{\sqrt{5}}{3} & -\frac{1}{6} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} |0 \otimes \frac{3}{2}\rangle \\ |1 \otimes \frac{1}{2}\rangle \\ |1 \otimes \frac{3}{2}\rangle \\ |1 \otimes \frac{1}{2}\rangle' \end{pmatrix}, \quad (2.2)$$

$$|\Sigma_c^*\bar{D}^*\rangle_{\frac{5}{2}} = \left|1 \otimes \frac{3}{2}\right\rangle, \quad (2.3)$$

where the subscripts on the left-hand side represent the total angular momentum $J = \frac{1}{2}, \frac{3}{2}, \frac{5}{2}$. The superscript ' on the right-hand side denotes the heavy-light structures of the $\Lambda_c\bar{D}^{(*)}$ systems. The rotation matrices in eqs. (2.1)–(2.3) will be denoted as R^J in the following. Because the $\Sigma_c^{(*)}$ and Λ_c are in different light spin multiplets, one needs four independent parameters to describe all transitions between various channels. Therefore, we introduce

$$C_{\frac{1}{2}} \equiv \left\langle s_Q \otimes \frac{1}{2} \left| \hat{\mathcal{H}}_I \right| s_Q \otimes \frac{1}{2} \right\rangle, \quad C_{\frac{3}{2}} \equiv \left\langle s_Q \otimes \frac{3}{2} \left| \hat{\mathcal{H}}_I \right| s_Q \otimes \frac{3}{2} \right\rangle, \quad (2.4)$$

for the transitions between the $\Sigma_c^{(*)}\bar{D}^{(*)}$ channels, and

$$C_{\frac{1}{2}}'' \equiv \left\langle s_Q \otimes \frac{1}{2} \left| \hat{\mathcal{H}}_I \right| s_Q \otimes \frac{1}{2} \right\rangle', \quad (2.5)$$

for those between the $\Lambda_c\bar{D}^{(*)}$ channels with $\hat{\mathcal{H}}_I$ the effective Hamiltonian respecting HQSS. For the transition between $\Sigma_c^{(*)}\bar{D}^{(*)}$ and $\Lambda_c\bar{D}^{(*)}$, we define

$$C_{\frac{1}{2}}' \equiv \left\langle s_Q \otimes \frac{1}{2} \left| \hat{\mathcal{H}}_I \right| s_Q \otimes \frac{1}{2} \right\rangle' = \left\langle s_Q \otimes \frac{1}{2} \left| \hat{\mathcal{H}}_I \right| s_Q \otimes \frac{1}{2} \right\rangle'. \quad (2.6)$$

In the heavy quark limit, the contact interactions defined above are independent of $s_Q = 0$ or 1. By virtue of the decomposition of eqs. (2.1)–(2.3), the leading order contact potentials

read

$$V_C^{\frac{1}{2}-} = \begin{pmatrix} \frac{1}{3}C_{\frac{1}{2}} + \frac{2}{3}C_{\frac{3}{2}} & \frac{2}{3\sqrt{3}}C_{\frac{1}{2}} - \frac{2}{3\sqrt{3}}C_{\frac{3}{2}} & \frac{1}{3}\sqrt{\frac{2}{3}}C_{\frac{1}{2}} - \frac{1}{3}\sqrt{\frac{2}{3}}C_{\frac{3}{2}} & 0 & \frac{1}{\sqrt{3}}C'_{\frac{1}{2}} \\ \frac{2}{3\sqrt{3}}C_{\frac{1}{2}} - \frac{2}{3\sqrt{3}}C_{\frac{3}{2}} & \frac{7}{9}C_{\frac{1}{2}} + \frac{2}{9}C_{\frac{3}{2}} & -\frac{\sqrt{2}}{9}C_{\frac{1}{2}} + \frac{\sqrt{2}}{9}C_{\frac{3}{2}} & \frac{1}{\sqrt{3}}C'_{\frac{1}{2}} & \frac{2}{3}C'_{\frac{1}{2}} \\ \frac{1}{3}\sqrt{\frac{2}{3}}C_{\frac{1}{2}} - \frac{1}{3}\sqrt{\frac{2}{3}}C_{\frac{3}{2}} & -\frac{\sqrt{2}}{9}C_{\frac{1}{2}} + \frac{\sqrt{2}}{9}C_{\frac{3}{2}} & \frac{8}{9}C_{\frac{1}{2}} + \frac{1}{9}C_{\frac{3}{2}} & -\sqrt{\frac{2}{3}}C'_{\frac{1}{2}} & \frac{\sqrt{2}}{3}C'_{\frac{1}{2}} \\ 0 & \frac{1}{\sqrt{3}}C'_{\frac{1}{2}} & -\sqrt{\frac{2}{3}}C'_{\frac{1}{2}} & C''_{\frac{1}{2}} & 0 \\ \frac{1}{\sqrt{3}}C'_{\frac{1}{2}} & \frac{2}{3}C'_{\frac{1}{2}} & \frac{\sqrt{2}}{3}C'_{\frac{1}{2}} & 0 & C''_{\frac{1}{2}} \end{pmatrix}, \quad (2.7)$$

$$V_C^{\frac{3}{2}-} = \begin{pmatrix} \frac{1}{9}C_{\frac{1}{2}} + \frac{8}{9}C_{\frac{3}{2}} & -\frac{1}{3\sqrt{3}}C_{\frac{1}{2}} + \frac{1}{3\sqrt{3}}C_{\frac{3}{2}} & -\frac{\sqrt{5}}{9}C_{\frac{1}{2}} + \frac{\sqrt{5}}{9}C_{\frac{3}{2}} & -\frac{1}{3}C'_{\frac{1}{2}} \\ -\frac{1}{3\sqrt{3}}C_{\frac{1}{2}} + \frac{1}{3\sqrt{3}}C_{\frac{3}{2}} & \frac{1}{3}C_{\frac{1}{2}} + \frac{2}{3}C_{\frac{3}{2}} & +\frac{1}{3}\sqrt{\frac{5}{3}}C_{\frac{1}{2}} - \frac{1}{3}\sqrt{\frac{5}{3}}C_{\frac{3}{2}} & \frac{1}{\sqrt{3}}C'_{\frac{1}{2}} \\ -\frac{\sqrt{5}}{9}C_{\frac{1}{2}} + \frac{\sqrt{5}}{9}C_{\frac{3}{2}} & \frac{1}{3}\sqrt{\frac{5}{3}}C_{\frac{1}{2}} - \frac{1}{3}\sqrt{\frac{5}{3}}C_{\frac{3}{2}} & \frac{5}{9}C_{\frac{1}{2}} + \frac{4}{9}C_{\frac{3}{2}} & \frac{\sqrt{5}}{3}C'_{\frac{1}{2}} \\ -\frac{1}{3}C'_{\frac{1}{2}} & \frac{1}{\sqrt{3}}C'_{\frac{1}{2}} & \frac{\sqrt{5}}{3}C'_{\frac{1}{2}} & C''_{\frac{1}{2}} \end{pmatrix}, \quad (2.8)$$

$$V_C^{\frac{5}{2}-} = C_{\frac{3}{2}}. \quad (2.9)$$

The transition between the elastic channels and the inelastic channels $J/\psi p$ and $\eta_c p$ can be obtained in a similar way. In the present work, we include both S and D waves for the $J/\psi p$ and $\eta_c p$ systems, since the three-momenta of the proton could be as large as 0.9 GeV and thus the D wave can be as important as the S wave in the energy region of interest. While the $|1 \otimes \frac{1}{2}\rangle$ component only couples to the $J/\psi p$ in S wave in the heavy quark limit, the $|1 \otimes \frac{3}{2}\rangle$ only couples to the $J/\psi p$ in D wave [40]. The $|0 \otimes \frac{1}{2}\rangle$ and the $|0 \otimes \frac{3}{2}\rangle$ components couple to the $\eta_c p$ channel in S wave and D wave, respectively. The coupling strengths of the S -wave $\Sigma_c^{(*)} \bar{D}^{(*)}$ to the $J/\psi p$ and $\eta_c p$ channels are related to each other via HQSS. We therefore need to introduce only two coupling constants,

$$\begin{aligned} g_S &\equiv \left\langle 1 \otimes \frac{1}{2} \left| \hat{\mathcal{H}}_I \right| J/\psi p \right\rangle_S = \left\langle 0 \otimes \frac{1}{2} \left| \hat{\mathcal{H}}_I \right| \eta_c p \right\rangle_S, \\ g_D k^2 &\equiv \left\langle 1 \otimes \frac{3}{2} \left| \hat{\mathcal{H}}_I \right| J/\psi p \right\rangle_D = \left\langle 0 \otimes \frac{3}{2} \left| \hat{\mathcal{H}}_I \right| \eta_c p \right\rangle_D, \end{aligned} \quad (2.10)$$

where k is the magnitude of the J/ψ (η_c) momentum in the $J/\psi p$ ($\eta_c p$) rest-frame. Employing eqs. (2.1)–(2.3), the constants g_S and g_D allow one to write the transition potentials $\mathcal{V}_{\alpha i}$ and $\mathcal{V}'_{\alpha i}$ between the α th elastic channel and the inelastic channels $J/\psi p$ and $\eta_c p$, respectively, as

$$\begin{aligned} \mathcal{V}_{\alpha 1}^J &= g_S R_{\alpha 2}^J, & \mathcal{V}_{\alpha 2}^J(k) &= g_D k^2 R_{\alpha 3}^J, & J &= \frac{1}{2}, \frac{3}{2}, \\ \mathcal{V}_{\alpha 1}^J &= 0, & \mathcal{V}_{\alpha 2}^J(k) &= g_D k^2, & J &= \frac{5}{2}, \\ \mathcal{V}'_{\alpha 1}^J &= g_S R_{\alpha 1}^J, & \mathcal{V}'_{\alpha 2}^J(k) &= 0, & J &= \frac{1}{2}, \\ \mathcal{V}'_{\alpha 1}^J &= 0 & \mathcal{V}'_{\alpha 2}^J(k) &= g_D k^2 R_{\alpha 1}^J, & J &= \frac{3}{2}, \\ \mathcal{V}'_{\alpha 1}^J &= 0, & \mathcal{V}'_{\alpha 2}^J(k) &= 0, & J &= \frac{5}{2}, \end{aligned} \quad (2.11)$$

where $\alpha = 1, 2, 3$ for $J = \frac{1}{2}, \frac{3}{2}$ and $\alpha = 1$ for $J = \frac{5}{2}$, and $i = 1, 2$ denote the S and D wave in the inelastic channels, respectively. The direct $J/\psi p$ and $\eta_c p$ interactions can be neglected since they are Okubo-Zweig-Lizuka suppressed and were found very weak in a recent lattice QCD calculation [82] (see also the estimate based on a coupled-channel model in ref. [83] leading to a $J/\psi p$ scattering length of the order of 10^{-3} fm). A similar assumption about neglecting the direct interactions between the inelastic $\Upsilon\pi$ and $h_b\pi$ channels was shown to be consistent with data for the $Z_b(10610)$ and $Z_b(10650)$ in a combined analysis of the $\Upsilon(10860)$ decays [79], and with the Dalitz plot analysis of the $\Upsilon\pi\pi$ final states from the $\Upsilon(10860)$ [84]. In addition, we assume that the effect from the interaction of the $\Lambda_c\bar{D}^{(*)}$ with the $J/\psi p$ and $\eta_c p$ channels is suppressed and can also be neglected. As long as the direct $J/\psi p$ and $\eta_c p$ interactions are neglected, the effect of these channels on the elastic channels can be included through an additional contribution [40, 79, 80, 85–87] to the potentials among the elastic channels. While the real parts of this contribution can be absorbed by redefining the contact terms $C_{\frac{1}{2}}$ and $C_{\frac{3}{2}}$ [80], the imaginary parts are included into the potentials as

$$V_{\text{in},\alpha\beta}^J(E) = -\frac{i}{2\pi E} \sum_{j=1}^2 m_{J/\psi} m_p \mathcal{V}_{\alpha j}^J \mathcal{V}_{\beta j}^J k - \frac{i}{2\pi E} \sum_{j=1}^2 m_{\eta_c} m_p \mathcal{V}_{\alpha j}^J \mathcal{V}_{\beta j}^J k. \quad (2.12)$$

As a result, the full effective potential for the elastic channels is the sum of the contact potential V_C^J , the effective potential from the inelastic channel V_{in}^J and the OPE potential $V_{\text{OPE}}^J(E, p, p')$

$$V^J(E, p, p') = V_C^J + V_{\text{in}}^J(E) + V_{\text{OPE}}^J(E, p, p'), \quad (2.13)$$

with E the total energy of the system, and p and p' the incoming and outgoing three-momenta. The OPE potential $V_{\text{OPE}}^J(E, p, p')$ will be discussed in the next subsection.

To describe the $\Lambda_b^0 \rightarrow J/\psi p K^-$ decay, one needs the bare weak production vertices as well. In this work, we only consider the S -wave $\Sigma_c^{(*)} \bar{D}^{(*)}$ bare production vertices for the $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K^-$ process, since the $\Sigma_c^{(*)} \bar{D}^{(*)}$ thresholds are close to the energy region of interest. It is stated in ref. [39] that the decay of the Λ_b into a spectator and $\Sigma_c^{(*)} \bar{D}^{(*)}$ is suppressed compared to that of $\Lambda_c \bar{D}^{(*)}$ due to isospin breaking or color suppression in the isospin conserving case. However, the color suppression factor is hard to quantify. In fact, with the b quark replaced by a c quark, were the color suppression effective, one would expect that the branching ratio of $\Lambda_c^+ \rightarrow \Sigma^0 K^+$ should be suppressed compared to that of $\Lambda_c^+ \rightarrow \Lambda K^+$, which, however, is in conflict to data, since these branching ratios are almost equal [71]. Reversely, this might suggest that the production strength of $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K^-$ could be comparable to that of $\Lambda_b^0 \rightarrow \Lambda_c \bar{D}^{(*)} K^-$. We take this as the motivation to neglect the $\Lambda_c \bar{D}^{(*)} K^-$ bare production vertex, since in the molecular picture advocated here the pentaquarks couple most strongly to the $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels. Also, it was shown in ref. [60] based on an EFT, if the system contains only two channels, that a dip must appear near the elastic threshold in the inelastic line shape if the elastic-channel interaction is strongly attractive and the production process goes dominantly through inelastic channels. On the other hand, data in the production channels driven by elastic channels should have a near-threshold peak. The fact that there are no obvious hints of dips in the vicinity of the

$\Sigma_c^{(*)} \bar{D}^{(*)}$ thresholds may then be regarded as yet another indication for the dominance of the elastic production mechanisms in the pentaquark system.

The weak bare production matrix elements can also be parametrized in terms of the $|s_Q \otimes j_\ell\rangle$ basis, i.e., $\mathcal{F}_n^J = \langle \Lambda_b | \hat{\mathcal{H}}_W | (s_Q \otimes j_\ell)_n^J K^- \rangle$, where $(s_Q \otimes j_\ell)_n^J$ refers to the n th state in the $|s_Q \otimes j_\ell\rangle$ basis in eqs. (2.1)–(2.3). With the seven parameters \mathcal{F}_n^J in total [40], the bare weak production amplitude for the α th elastic channel for a given J reads

$$P_\alpha^J = \sum_n R_{\alpha n}^J \mathcal{F}_n^J. \quad (2.14)$$

Therefore, the bare weak production amplitudes for $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K^-$ with the S wave $\Sigma_c^{(*)} \bar{D}^{(*)}$ in $J = \frac{1}{2}, \frac{3}{2}$, and $\frac{5}{2}$ read

$$\begin{aligned} P^{\frac{1}{2}} &= \left(\frac{1}{2} \mathcal{F}_1^{\frac{1}{2}} + \frac{1}{2\sqrt{3}} \mathcal{F}_2^{\frac{1}{2}} + \sqrt{\frac{2}{3}} \mathcal{F}_3^{\frac{1}{2}}, \frac{1}{2\sqrt{3}} \mathcal{F}_1^{\frac{1}{2}} + \frac{5}{6} \mathcal{F}_2^{\frac{1}{2}} - \frac{\sqrt{2}}{3} \mathcal{F}_3^{\frac{1}{2}}, \sqrt{\frac{2}{3}} \mathcal{F}_1^{\frac{1}{2}} - \frac{\sqrt{2}}{3} \mathcal{F}_2^{\frac{1}{2}} - \frac{1}{3} \mathcal{F}_3^{\frac{1}{2}} \right)^T, \\ P^{\frac{3}{2}} &= \left(\frac{1}{\sqrt{3}} \mathcal{F}_1^{\frac{3}{2}} - \frac{1}{3} \mathcal{F}_2^{\frac{3}{2}} + \frac{\sqrt{5}}{3} \mathcal{F}_3^{\frac{3}{2}}, -\frac{1}{2} \mathcal{F}_1^{\frac{3}{2}} + \frac{1}{\sqrt{3}} \mathcal{F}_2^{\frac{3}{2}} + \frac{1}{2} \sqrt{\frac{5}{3}} \mathcal{F}_3^{\frac{3}{2}}, \frac{1}{2} \sqrt{\frac{5}{3}} \mathcal{F}_1^{\frac{3}{2}} + \sqrt{\frac{5}{3}} \mathcal{F}_2^{\frac{3}{2}} - \frac{1}{6} \mathcal{F}_3^{\frac{3}{2}} \right)^T, \\ P^{\frac{5}{2}} &= \mathcal{F}_1^{\frac{5}{2}}. \end{aligned} \quad (2.15)$$

2.2 One-pion-exchange potentials

The LO OPE potential can be obtained using the effective Lagrangian for the axial coupling of the pions to the charmed mesons and baryons [88, 89],

$$\mathcal{L} = \frac{g_1}{4} \langle \sigma \cdot u_{ab} \bar{H}_b \bar{H}_a^\dagger \rangle + i g_2 \epsilon_{ijk} S_{ab}^{i\dagger} u_{bc}^j S_{ca}^k - \frac{1}{\sqrt{2}} g_3 (S_{ab}^{i\dagger} u_{bc}^i T_{ca} + T_{ab}^\dagger u_{bc}^i S_{ca}^i), \quad (2.16)$$

where $\langle \dots \rangle$ denotes the trace in the spinor space and σ represents the Pauli matrices. The subindices a, b, c denote the light-flavor content, and the superindices i, j, k denote the polarization. S^i and \bar{H} are the heavy quark spin doublets for the ground states (Σ_c, Σ_c^*) and (\bar{D}, \bar{D}^*) [90],

$$S^i = \frac{1}{\sqrt{3}} \sigma^i \Sigma_c + \Sigma_c^{*i}, \quad \bar{H} = -\bar{D} + \sigma \cdot \bar{D}^*, \quad (2.17)$$

with

$$S_c^{(*)} = \begin{pmatrix} \Sigma_c^{(*)++} & \frac{1}{\sqrt{2}} \Sigma_c^{(*)+} \\ \frac{1}{\sqrt{2}} \Sigma_c^{(*)+} & \Sigma_c^{(*)0} \end{pmatrix}, \quad \bar{D}^{(*)} = \begin{pmatrix} \bar{D}^{(*)0} \\ \bar{D}^{(*)-} \end{pmatrix}. \quad (2.18)$$

The Λ_c^+ is described by the spinor field T ,

$$T = \begin{pmatrix} 0 & \frac{1}{\sqrt{2}} \Lambda_c^+ \\ -\frac{1}{\sqrt{2}} \Lambda_c^+ & 0 \end{pmatrix}, \quad (2.19)$$

and the pions are collected in $\mathbf{u} = -\nabla \Phi / F_\pi + \mathcal{O}(\Phi^3)$, where $\Phi = \boldsymbol{\tau} \cdot \boldsymbol{\pi}$ with $\boldsymbol{\tau}$ and $\boldsymbol{\pi}$ the Pauli matrices in the isospin space and the pion fields, and $F_\pi = 92.1$ MeV is the pion decay constant. From the width of $D^{*+} \rightarrow D^0 \pi^+$ one gets $g_1 = 0.57$, and the couplings $g_2 = 0.42$ and $g_3 = 0.71$ are taken from a lattice QCD calculation [91]. The signs of these couplings are fixed from the lattice results [91].

| J^P | S wave | D wave |
|------------------------------|--|---|
| $\left(\frac{1}{2}\right)^-$ | $\Sigma_c \bar{D}, \Sigma_c \bar{D}^*, \Sigma_c^* \bar{D}^*, \Lambda_c \bar{D}, \Lambda_c \bar{D}^*$ | $\Sigma_c \bar{D}_{\frac{3}{2}}^*, \Sigma_c^* \bar{D}, \Sigma_c^* \bar{D}_{\frac{3}{2}}^*, \Sigma_c^* \bar{D}_{\frac{5}{2}}^*, \Lambda_c \bar{D}_{\frac{3}{2}}^*$ |
| $\left(\frac{3}{2}\right)^-$ | $\Sigma_c \bar{D}^*, \Sigma_c^* \bar{D}, \Sigma_c^* \bar{D}^*, \Lambda_c \bar{D}^*$ | $\Sigma_c \bar{D}, \Sigma_c \bar{D}_{\frac{1}{2}}^*, \Sigma_c \bar{D}_{\frac{3}{2}}^*, \Sigma_c^* \bar{D}, \Sigma_c^* \bar{D}_{\frac{1}{2}}^*, \Sigma_c^* \bar{D}_{\frac{3}{2}}^*, \Sigma_c^* \bar{D}_{\frac{5}{2}}^*, \Lambda_c \bar{D}, \Lambda_c \bar{D}_{\frac{1}{2}}^*, \Lambda_c \bar{D}_{\frac{3}{2}}^*$ |
| $\left(\frac{5}{2}\right)^-$ | $\Sigma_c^* \bar{D}^*$ | $\Sigma_c \bar{D}, \Sigma_c \bar{D}_{\frac{1}{2}}^*, \Sigma_c \bar{D}_{\frac{3}{2}}^*, \Sigma_c^* \bar{D}, \Sigma_c^* \bar{D}_{\frac{1}{2}}^*, \Sigma_c^* \bar{D}_{\frac{3}{2}}^*, \Sigma_c^* \bar{D}_{\frac{5}{2}}^*, \Lambda_c \bar{D}, \Lambda_c \bar{D}_{\frac{1}{2}}^*, \Lambda_c \bar{D}_{\frac{3}{2}}^*$ |

Table 1. Coupled channels for both S - and D -wave $\Sigma_c^{(*)} \bar{D}^{(*)}$, $\Lambda_c \bar{D}^{(*)}$ systems considered in the present work. Whenever the two particles can couple to different spins, we use a subindex to denote their total spin. The states given in this table appear as basis vectors for the potentials discussed in the text.

Once the OPE is considered, the corresponding tensor force, whose importance is well-known for few-nucleon systems, generates a mixture between S waves and D waves, which can have a sizable impact on the line shapes between thresholds [77, 79, 80]. The quantum numbers of the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\Lambda_c \bar{D}^{(*)}$ systems taken into account in this work are listed in table 1.

All pentaquarks so far were observed in the $J/\psi p$ final state and therefore have isospin 1/2. The corresponding isospin wave functions can therefore be related to the particle channels via

$$P_c^+ = \sqrt{\frac{2}{3}} \Sigma_c^{(*)++} D^{(*)-} - \sqrt{\frac{1}{3}} \Sigma_c^{(*)+} \bar{D}^{(*)0}. \quad (2.20)$$

Starting from the potentials

$$\begin{aligned} V_{\Sigma_c^{(*)+} \bar{D}^{(*)0} \rightarrow \Sigma_c^{(*)+} \bar{D}^{(*)0}}^{\text{OPE}} &= 0, \\ V_{\Sigma_c^{(*)++} D^{(*)-} \rightarrow \Sigma_c^{(*)++} D^{(*)-}}^{\text{OPE}} &= -\frac{1}{\sqrt{2}} V_{\Sigma_c^{(*)+} \bar{D}^{(*)0} \rightarrow \Sigma_c^{(*)++} D^{(*)-}}^{\text{OPE}} = -\frac{1}{\sqrt{2}} V_{\Sigma_c^{(*)++} D^{(*)-} \rightarrow \Sigma_c^{(*)+} \bar{D}^{(*)0}}^{\text{OPE}}, \\ V_{\Sigma_c^{(*)++} D^{(*)-} \rightarrow \Lambda_c^+ \bar{D}^{(*)0}}^{\text{OPE}} &= -\sqrt{2} V_{\Sigma_c^{(*)+} \bar{D}^{(*)0} \rightarrow \Lambda_c^+ \bar{D}^{(*)0}}^{\text{OPE}}, \end{aligned} \quad (2.21)$$

one thus gets

$$\begin{aligned} V_{\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)}}^{\text{OPE}} &= 2 V_{\Sigma_c^{(*)++} D^{(*)-} \rightarrow \Sigma_c^{(*)++} D^{(*)-}}^{\text{OPE}}, \\ V_{\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Lambda_c \bar{D}^{(*)}}^{\text{OPE}} &= \sqrt{\frac{3}{2}} V_{\Sigma_c^{(*)++} D^{(*)-} \rightarrow \Lambda_c^+ \bar{D}^{(*)0}}^{\text{OPE}}. \end{aligned} \quad (2.22)$$

In the framework of time-ordered-perturbation theory (TOPT), the OPE potentials acquire two parts corresponding to the two contributions in figure 1, where the vertical lines indicate the intermediate three-body states. In some cases, for example, for the $\Sigma_c \bar{D} \rightarrow \Lambda_c \bar{D}^*$ transition, the intermediate state $\Lambda_c \bar{D} \pi$ can be on shell in the energy region where all P_c states reside. Thus, the effect of the three-body cut has to be taken into account in the potential and in the $\Sigma_c^{(*)}$ self-energy loops, see eqs. (A.5)–(A.7) in appendix A for the relevant potentials and section 3 for the self-energy loop.

2.3 Next-to-leading-order contact terms

In subsection 2.1, we construct the LO contact potentials using the heavy-light spin structure decomposition $|s_Q \otimes j_\ell\rangle$. Alternatively, one can also obtain those potentials using

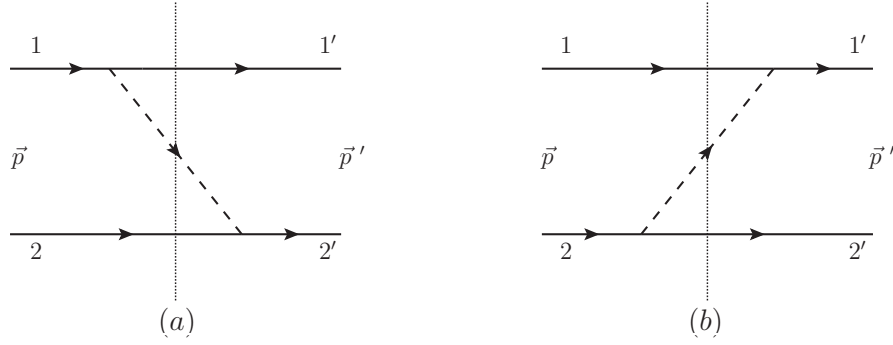

Figure 1. Diagrams in TOPT responsible for the two contributions to the OPE potential. The solid line represents the $\Sigma_c^{(*)}$, Λ_c and $\bar{D}^{(*)}$, the dashed line denotes the pion field.

an effective Lagrangian. For the $\Sigma_c^{(*)}\bar{D}^{(*)}$ and $\Lambda_c\bar{D}^{(*)}$ channels, the effective Lagrangian reads [21, 32, 66]

$$\begin{aligned} \mathcal{L}_{\text{LO}} = & -C_a \mathbf{S}_{ab}^\dagger \cdot \mathbf{S}_{ba} \langle \bar{H}_c^\dagger \bar{H}_c \rangle - C_b i \epsilon_{jik} S_{ab}^{j\dagger} S_{ba}^k \langle \bar{H}_c^\dagger \sigma^i \bar{H}_c \rangle \\ & + C_c \left(S_{ab}^{i\dagger} T_{ca} \langle \bar{H}_c^\dagger \sigma^i \bar{H}_b \rangle - T_{ca}^\dagger S_{ab}^i \langle \bar{H}_b^\dagger \sigma^i \bar{H}_c \rangle \right) - C_d T_{ab}^\dagger T_{ba} \langle \bar{H}_c^\dagger \bar{H}_c \rangle, \end{aligned} \quad (2.23)$$

where the contact potentials C_a , C_b , C_c and C_d are related to those in eqs. (2.7)–(2.9) as

$$\begin{aligned} C_a &= \frac{1}{3}C_{\frac{1}{2}} + \frac{2}{3}C_{\frac{3}{2}}, & C_b &= \frac{1}{3}(C_{\frac{3}{2}} - C_{\frac{1}{2}}), \\ C_c &= \frac{2}{3}C'_{\frac{1}{2}}, & C_d &= C''_{\frac{1}{2}}. \end{aligned} \quad (2.24)$$

The transitions between the elastic and inelastic channels in eqs. (2.11) can also be obtained using the effective Lagrangian respecting the HQSS [32]:

$$\mathcal{L}_{\text{ine}} = \frac{g_S}{\sqrt{3}} N^\dagger \sigma^i \bar{H} J^\dagger S^i - \sqrt{3} g_D N^\dagger \sigma^i \bar{H} (\partial^i \partial^j - \frac{1}{3} \delta^{ij} \partial^2) J^\dagger S^j, \quad (2.25)$$

where N denotes the nucleon doublet, and $J = -\eta_c + \boldsymbol{\sigma} \cdot \boldsymbol{\psi}$ contains the ground state charmonium fields.

It was noticed in refs. [73, 77] for $B^{(*)}\bar{B}^*$ scattering that the NLO contact terms which contribute to the S - D transitions need to be promoted to LO to tame the ultraviolet (UV) divergence associated with the S - D OPE potentials in the course of iterations. The S - S NLO contact terms, however, play a subleading role resulting only in a marginal improvement in the fits to the Z_b line shapes. In this work, we proceed analogously, and we also find that once the full OPE potential is included dynamically the S - D NLO contact terms are required to obtain regulator-independent results. The S - S NLO contact terms are expected to play a marginal role also in the pentaquark system. More details on this

will be given in section 4.2. To this end, we construct the NLO effective Lagrangian

$$\begin{aligned}
 \mathcal{L}_{\text{NLO}} = & -D_a^{SS} \left(\partial^i \mathbf{S}_{ab}^\dagger \cdot \mathbf{S}_{ba} \langle \partial^i \bar{H}_c^\dagger \bar{H}_c \rangle + \mathbf{S}_{ab}^\dagger \cdot \partial^i \mathbf{S}_{ba} \langle \bar{H}_c^\dagger \partial^i \bar{H}_c \rangle \right) \\
 & - D_b^{SS} i \epsilon_{jik} \left(\partial^\ell S_{ab}^{j\dagger} S_{ba}^k \langle \partial^\ell \bar{H}_c^\dagger \sigma^i \bar{H}_c \rangle + S_{ab}^{j\dagger} \partial^\ell S_{ba}^k \langle \bar{H}_c^\dagger \sigma^i \partial^\ell \bar{H}_c \rangle \right) \\
 & - D_b^{SD} i \epsilon_{jik} \left[\partial_i S_j^\dagger S_k \langle \partial_\ell \bar{H}^\dagger \sigma_\ell \bar{H} \rangle + \partial_\ell S_j^\dagger S_k \langle \partial_i \bar{H}^\dagger \sigma_\ell \bar{H} \rangle - \frac{2}{3} \partial_\ell S_j^\dagger S_k \langle \partial_\ell \bar{H}^\dagger \sigma_i \bar{H} \rangle \right. \\
 & \left. + S_j^\dagger \partial_i S_k \langle \bar{H}^\dagger \sigma_\ell \partial_\ell \bar{H} \rangle + S_j^\dagger \partial_\ell S_k \langle \bar{H}^\dagger \sigma_\ell \partial_i \bar{H} \rangle - \frac{2}{3} S_j^\dagger \partial_\ell S_k \langle \bar{H}^\dagger \partial_\ell \sigma_i \bar{H} \rangle \right] \\
 & + \frac{2}{3} \sqrt{2} D_c^{SD} \left[\partial^i S_{ab}^{i\dagger} T_{ca} \langle \partial^j \bar{H}_c^\dagger \sigma^j \bar{H}_b \rangle + \partial^j S_{ab}^{i\dagger} T_{ca} \langle \partial^i \bar{H}_c^\dagger \sigma^j \bar{H}_b \rangle - \frac{2}{3} \partial^j S_{ab}^{i\dagger} T_{ca} \langle \partial^j \bar{H}_c^\dagger \sigma^i \bar{H}_b \rangle \right. \\
 & - \partial^i T_{ca}^\dagger S_{ab}^i \langle \partial^j \bar{H}_b^\dagger \sigma^j \bar{H}_c \rangle - \partial^j T_{ca}^\dagger S_{ab}^i \langle \partial^i \bar{H}_b^\dagger \sigma^j \bar{H}_c \rangle + \frac{2}{3} \partial^j T_{ca}^\dagger S_{ab}^i \langle \partial^j \bar{H}_b^\dagger \sigma^i \bar{H}_c \rangle \\
 & + S_{ab}^{i\dagger} \partial^i T_{ca} \langle \bar{H}_c^\dagger \sigma^j \partial^j \bar{H}_b \rangle + S_{ab}^{i\dagger} \partial^j T_{ca} \langle \bar{H}_c^\dagger \sigma^j \partial^i \bar{H}_b \rangle - \frac{2}{3} S_{ab}^{i\dagger} \partial^j T_{ca} \langle \bar{H}_c^\dagger \sigma^i \partial^j \bar{H}_b \rangle \\
 & \left. - T_{ca}^\dagger \partial^i S_{ab}^i \langle \bar{H}_b^\dagger \sigma^j \partial^j \bar{H}_c \rangle - T_{ca}^\dagger \partial^j S_{ab}^i \langle \bar{H}_b^\dagger \sigma^j \partial^i \bar{H}_c \rangle + \frac{2}{3} T_{ca}^\dagger \partial^j S_{ab}^i \langle \bar{H}_b^\dagger \sigma^i \partial^j \bar{H}_c \rangle \right] \\
 & + D_d^{SS} \left(\partial^i T_{ab}^\dagger T_{ba} \langle \partial^i \bar{H}_c^\dagger \bar{H}_c \rangle + T_{ab}^\dagger \partial^i T_{ba} \langle \bar{H}_c^\dagger \partial^i \bar{H}_c \rangle \right), \tag{2.26}
 \end{aligned}$$

where the $D_{a(b,d)}^{SS}$ and the $D_{b(c)}^{SD}$ are responsible for the contact S - S and S - D transitions, respectively. Specifically, D_b^{SD} contributes to the $O(Q^2)$ S - D transitions $\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)}$, while D_c^{SD} to $\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Lambda_c \bar{D}^{(*)}$. The NLO contact potential matrix, on the basis of the S and D waves, for the scattering process $12 \rightarrow 1'2'$ with p and p' for the incoming and outgoing three-momenta, respectively, reads

$$V_{\text{NLO}}^J(p, p') = \begin{pmatrix} (p^2 + p'^2) V_{SS}^J & p'^2 V_{SD}^J \\ p^2 (V_{SD}^J)^T & 0 \end{pmatrix}. \tag{2.27}$$

The potential V_{SD}^J for the channels listed in table 1 can be written in the matrix form (where the columns and rows are given for the channels in order they appear in the table) as

$$\begin{aligned}
 V_{SD}^{\frac{1}{2}} = & -\frac{128}{3} \begin{pmatrix} \frac{D_b^{SD}}{4\sqrt{6}} & 0 & -\frac{D_b^{SD}}{8\sqrt{30}} & -\frac{1}{8}\sqrt{\frac{3}{10}} D_b^{SD} & \frac{D_c^{SD}}{8\sqrt{3}} \\ \frac{D_b^{SD}}{12\sqrt{2}} & -\frac{D_b^{SD}}{8\sqrt{6}} & \frac{6\sqrt{10}}{7D_b^{SD}} & -\frac{8\sqrt{10}}{D_b^{SD}} & -\frac{24}{D_c^{SD}} \\ \frac{48}{16\sqrt{3}} & -\frac{8\sqrt{6}}{7D_b^{SD}} & \frac{48\sqrt{5}}{8\sqrt{5}} & \frac{1}{8}\sqrt{\frac{3}{5}} D_c^{SD} & 0 \\ \frac{8\sqrt{3}}{24} & \frac{D_c^{SD}}{8\sqrt{3}} & -\frac{D_c^{SD}}{6\sqrt{5}} & \frac{D_c^{SD}}{8\sqrt{5}} & 0 \end{pmatrix}, \tag{2.28} \\
 V_{SD}^{\frac{3}{2}} = & -\frac{128}{3} \begin{pmatrix} -\frac{D_b^{SD}}{8\sqrt{3}} & \frac{D_b^{SD}}{24} & -\frac{D_b^{SD}}{12} & \frac{D_b^{SD}}{16\sqrt{3}} & -\frac{D_b^{SD}}{48\sqrt{2}} & -\frac{D_b^{SD}}{48\sqrt{5}} & \frac{1}{16}\sqrt{\frac{7}{10}} D_b^{SD} & -\frac{D_c^{SD}}{8\sqrt{6}} & \frac{D_c^{SD}}{24\sqrt{2}} & -\frac{D_c^{SD}}{12\sqrt{2}} \\ 0 & \frac{16\sqrt{3}}{16\sqrt{3}} & \frac{16\sqrt{3}}{16\sqrt{3}} & 0 & \frac{16\sqrt{6}}{16\sqrt{6}} & \frac{4\sqrt{15}}{4\sqrt{15}} & \frac{1}{16}\sqrt{\frac{21}{10}} D_b^{SD} & 0 & -\frac{D_c^{SD}}{8\sqrt{6}} & -\frac{D_c^{SD}}{8\sqrt{6}} \\ \frac{D_b^{SD}}{16\sqrt{15}} & -\frac{12\sqrt{5}}{12\sqrt{5}} & -\frac{48\sqrt{5}}{48\sqrt{5}} & \frac{4\sqrt{15}}{4\sqrt{15}} & -\frac{48\sqrt{10}}{48\sqrt{10}} & -\frac{15}{15} & \frac{1}{80}\sqrt{\frac{7}{2}} D_b^{SD} & -\frac{D_c^{SD}}{8\sqrt{30}} & \frac{D_c^{SD}}{6\sqrt{10}} & \frac{D_c^{SD}}{24\sqrt{10}} \\ -\frac{D_c^{SD}}{8\sqrt{6}} & \frac{D_c^{SD}}{24\sqrt{2}} & -\frac{D_c^{SD}}{12\sqrt{2}} & -\frac{D_c^{SD}}{8\sqrt{6}} & \frac{D_c^{SD}}{48} & \frac{D_c^{SD}}{24\sqrt{10}} & -\frac{1}{16}\sqrt{\frac{7}{5}} D_c^{SD} & 0 & 0 & 0 \end{pmatrix}, \\
 V_{SD}^{\frac{5}{2}} = & -\frac{128}{3} \left(-\frac{D_b^{SD}}{8\sqrt{10}} - \frac{D_b^{SD}}{8\sqrt{30}} - \frac{D_b^{SD}}{16}\sqrt{\frac{7}{15}} - \frac{D_b^{SD}}{16}\sqrt{\frac{7}{5}} \frac{D_b^{SD}}{8\sqrt{15}} - \frac{D_b^{SD}}{80}\sqrt{\frac{7}{3}} - \frac{D_b^{SD}}{20}\sqrt{\frac{7}{2}} \frac{D_c^{SD}}{8\sqrt{5}} \frac{D_c^{SD}}{8\sqrt{15}} \frac{D_c^{SD}}{8}\sqrt{\frac{7}{30}} \right).
 \end{aligned}$$

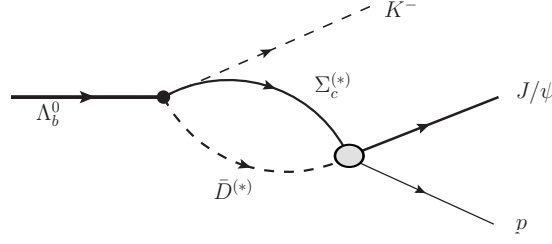

Figure 2. Diagram for the $\Lambda_b^0 \rightarrow J/\psi p K^-$ decay through $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K^-$ following the final state interactions.

By comparing to the S - D OPE potentials in eqs. (A.5)–(A.7), it is easy to see that the NLO S - D contact potential has the same structure as the corresponding OPE potentials. Indeed, the coefficients for the $\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)}$ transitions are exactly the same, while those for the transitions $\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Lambda_c \bar{D}^{(*)}$ differ by an overall coefficient, which can be absorbed into a redefined D_c^{SD} . The same holds for the structure of V_{SS}^J compared to the LO contact potentials in eqs. (2.7)–(2.9). Thus, V_{SS}^J is not shown explicitly here.

3 Lippmann-Schwinger equation with dynamic width of $\Sigma_c^{(*)}$

With the above ingredients, one can obtain the production amplitude satisfying unitarity by solving the LSEs. A diagrammatic representation thereof is shown in figure 2. Here we treat the pion relativistically and employ the relativistic mass-energy relations for $\Sigma_c^{(*)}$, $\bar{D}^{(*)}$ and Λ_c . To be consistent, we employ the LSEs with relativistic Green functions. The T -matrix for $\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)}$ scattering is given by the LSE,

$$T_{\alpha\gamma}^J(E, p, p') = V_{\alpha\gamma}^J(E, p, p') - \sum_{\beta} \int \frac{d^3\mathbf{q}}{(2\pi)^3} V_{\alpha\beta}^J(E, p, q) G_{\beta}(E, q) T_{\beta\gamma}^J(E, q, p'), \quad (3.1)$$

where the two-body propagator reads [92]

$$G_{\beta}(E, \mathbf{q}) = \frac{m_{\Sigma_c^{(*)}} m_{D^{(*)}}}{E_{\Sigma_c^{(*)}}(\mathbf{q}) E_{D^{(*)}}(\mathbf{q})} \frac{1}{E_{\Sigma_c^{(*)}}(\mathbf{q}) + E_{D^{(*)}}(\mathbf{q}) - E - \tilde{\Sigma}_R(s, m_{\Sigma_c^{(*)}})/(2E_{\Sigma_c^{(*)}}(\mathbf{q}))}, \quad (3.2)$$

with

$$s = (E - E_{D^{(*)}}(\mathbf{q}))^2 - \mathbf{q}^2 \quad (3.3)$$

for the off-shell $\Sigma_c^{(*)}$ resonance and $\tilde{\Sigma}_R(s, m_{\Sigma_c^{(*)}})$ the renormalized self-energy loop diagram with $E_i = \sqrt{\mathbf{q}^2 + m_i^2}$. The self-energy function $\tilde{\Sigma}_R(s, m_{\Sigma_c^{(*)}})$ can be evaluated from the diagram in figure 3, since the width of the $\Sigma_c^{(*)}$ is almost saturated by the two-body decay into the $\Lambda_c \pi$ [71]. For simplicity, here we use a more pragmatic way and consider only the unitarity-driven part of the loop diagram, which generates a relevant three-body cut from the $\Lambda_c \bar{D} \pi$ threshold. We expect that the principal value part of the loop can be largely absorbed into renormalization of the $\Sigma_c^{(*)}$ mass. Therefore, the self-energy function reduces to

$$\tilde{\Sigma}_R(s, m_{\Sigma_c^{(*)}}) = ig^2 \frac{p^3}{\sqrt{s}}, \quad (3.4)$$

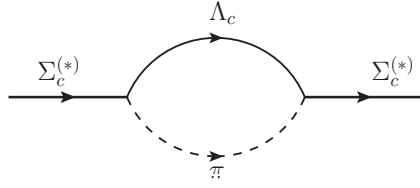

Figure 3. Loop diagrams of the self-energy for $\Sigma_c^{(*)}$.

where $p = \lambda^{1/2}(s, m_{\Lambda_c}^2, m_\pi^2)/2\sqrt{s}$ with Källén function $\lambda(a, b, c) = a^2 + b^2 + c^2 - 2ab - 2bc - 2ca$ and g is set to reproduce the physical width of the $\Sigma_c^{(*)}$, i.e., $\tilde{\Sigma}_R(m_{\Sigma_c^{(*)}}^2, m_{\Sigma_c^{(*)}}) = im_{\Sigma_c^{(*)}}\Gamma_{\Sigma_c^{(*)}}$. The effect of the \bar{D}^* width can be safely neglected as it is only several tens of keV, i.e., it is three orders of magnitude smaller than that of the $\Sigma_c^{(*)}$. The widths of the \bar{D} and Λ_c are even smaller than that of \bar{D}^* since both states decay only via the weak interaction, and thus are also negligible. Neglecting the energy-dependence of the self-energy, i.e., employing $\tilde{\Sigma}_R(s, m_{\Sigma_c^{(*)}}) = im_{\Sigma_c^{(*)}}\Gamma_{\Sigma_c^{(*)}}$ in the LSEs, the two-body propagator eq. (3.2) reduces to the form used in ref. [40] in the nonrelativistic limit.

To describe the $J/\psi p$ mass distribution, we work in terms of the production amplitudes rather than the scattering amplitudes. The LSE for the physical production amplitude of the α th elastic channel $U_\alpha(E, p)^J$ reads

$$U_\alpha^J(E, p) = P_\alpha^J - \sum_\beta \int \frac{d^3\mathbf{q}}{(2\pi)^3} V_{\alpha\beta}^J(E, p, q) G_\beta(E, q) U_\beta^J(E, q), \quad (3.5)$$

where P_α denotes the bare production vertices in eq. (2.15). Note that we only include the S -wave $\Sigma_c^{(*)}\bar{D}^{(*)}$ production source in LSE, while the sources from the other channels are neglected, as discussed above. The source corresponding to production of the D -wave $\Sigma_c^{(*)}\bar{D}^{(*)}$ is also neglected due to the centrifugal barrier as discussed above. As a result of these simplifying assumptions, the production amplitude, $U_i^{(\prime)J}$, for the i th $J/\psi p$ ($\eta_c p$) inelastic channel is simply given by

$$U_i^{(\prime)J}(E, k) = - \sum_\beta \int \frac{d^3\mathbf{q}}{(2\pi)^3} \mathcal{V}_{i\beta}^{(\prime)J}(k) G_\beta(E, q) U_\beta^J(E, q). \quad (3.6)$$

To render the integrals in the LSEs well defined one needs to introduce a regulator, with a cutoff larger than all typical three-momenta scales related to coupled-channel dynamics. In what follows, we will discuss the results obtained for a hard cutoff Λ set to 1 GeV for the pure contact potentials, namely scheme I, and to 1.3 GeV for the case including OPE potentials, i.e., schemes II and III, as discussed below. However, we have checked that the final results barely depend on the cutoff value, when Λ is varied from 0.7 GeV to 1.7 GeV for the contact scheme, and from 1.0 to 1.7 GeV for the schemes including OPE potentials, once the mentioned S - D counter terms are included (in the case of solution B).

4 Fit results

With the decay amplitude from eq. (3.6), we are in a position to fit the $J/\psi p$ invariant mass distribution of the decay $\Lambda_b^0 \rightarrow J/\psi p K^-$ by LHCb [17]. The possible contributions from misidentified non- Λ_b^0 events, the Λ^* resonances coupled to the pK^- , and possibly additional broad P_c^+ structures are modelled by a smooth incoherent background [40]

$$f_{\text{bgd}}(E) = b_0 + b_1 E^2 + b_2 E^4 + \frac{g_r^2}{(m - E)^2 + \Gamma^2/4}, \quad (4.1)$$

where b_0 , b_1 , b_2 , g_r , m and Γ are the parameters to be determined by fitting to the data. The other variations of the background used in the experimental analysis [17] are also considered, and the results are similar. In principle, the contributions from the Λ^* resonances coupled to the pK^- and the possible broad P_c^+ states living in the partial waves we are studying should be summed coherently at the amplitude level.³ However, the three P_c states we are interested in are so narrow that, similar to refs. [15, 17], our one-dimensional analysis is expected to be insensitive to the possible broad structures. In addition, a direct sum of our signal amplitudes and the coherent background would violate unitarity, unless the resonance structures in the background emerge in the channels included in the present framework. Since there is no evidence for such states so far, we restrict ourselves to the incoherent background given in eq. (4.1). As for the Λ^* contributions, it will be discussed below that the position of the poles in our analysis is robust with respect to three different LHCb datasets used in the fits, including the fit with the kinematic constraint $m_{Kp} > 1.9 \text{ GeV}$ which cuts more than 80% of the Λ^* hyperons. The sensitivity of the poles to the experimental input will be included in the uncertainty estimate. The parameters of the background in various fits can be found in appendix B.

In this work, we consider three different fit schemes:

- scheme I: the LO contact potentials for the $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels are implemented including the couplings of the elastic channels to the S - and D -wave $J/\psi p$ and $\eta_c p$ channels;
- scheme II: the OPE potentials supplemented by the NLO S - D contact terms for the $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels are added to the potential of I;
- scheme III: the explicit $\Lambda_c \bar{D}^{(*)}$ channels are added to scheme II, including the LO contact potentials, the OPE potentials and the NLO S - D contact terms.

In this analysis, we do not consider isospin symmetry breaking effects, which can be important to the isospin-breaking decay modes [20, 93], but have little effect on the description of the line shapes in the isospin-conserving $J/\psi p$ channel. The masses of particles used in the calculation are collected in eq. (B.1) in appendix B. For all results shown a Gaussian convolution of the theoretical distributions with the mass resolution of the experiment [17] is employed.

³Note however that the preferred parity of the broad $P_c(4380)$ is opposite to that of the $P_c(4450)$ in ref. [17] and thus to all pentaquarks considered here.

Following the fit schemes introduced above, we improve our previous framework presented in ref. [40], where only the $\Sigma_c^{(*)}\bar{D}^{(*)}$ and $J/\psi p$ channels were considered explicitly and all other inelastic channels were parametrized as imaginary parts of the short ranged operators, in several steps.

4.1 Scheme I: contact potentials

4.1.1 Including the $\eta_c p$ channel

The new $\eta_c p$ channel comes without additional unknown parameters, since the transitions between the $\Sigma_c^{(*)}\bar{D}^{(*)}$ and $\eta_c p$ channels are related to those between $\Sigma_c^{(*)}\bar{D}^{(*)}$ and $J/\psi p$ channels by HQSS, as discussed in section 2.1. In addition, a relativistic form of the two-body propagator eq. (3.2) and the energy-dependence of the width for the $\Sigma_c^{(*)}$, eq. (3.4), are employed in this work. As the first step, we do not consider coupled-channel effects from the $\Lambda_c\bar{D}^{(*)}$ channels, i.e., for the fits discussed here we set both $C'_{\frac{1}{2}}$ and $C''_{\frac{1}{2}}$ to zero. From now on we further assume that the widths of the P_c states are saturated by the channels included — in this subsection those are $J/\psi p$, $\eta_c p$, and the elastic channels (including those via the decays of the $\Sigma_c^{(*)}$). Therefore, no additional imaginary contact potentials as in ref. [40] need to be introduced and unitarity is realized.

Three data sets of the $m_{J/\psi p}$ distribution given in ref. [17] are used in fits. The $m_{J/\psi p}$ distribution with $m_{Kp} > 1.9$ GeV can effectively remove over 80% of the Λ^* contributions and the P_c signals are enhanced in the $m_{J/\psi p}$ distribution by applying $\cos\theta_{P_c}$ -dependent weights to each event candidate, with θ_{P_c} the angle between the K^- and the J/ψ in the P_c rest frame [17]. In analogy to what was reported in ref. [40], also with our modified model, two solutions, called *A* and *B*, describing the data almost equally well are found as shown in figure 4.

To study the poles in an n -channel problem, a multi-sheet Riemann surface in the complex energy plane is invoked. We only consider the RSs associated to the four elastic channels $\Sigma_c^{(*)}\bar{D}^{(*)}$, since all inelastic thresholds are remote and their impact on the poles near the elastic thresholds is marginal. Assuming that all four elastic channels can couple to each other, there are $2^4 = 16$ RSs in total labeled as $\text{RS}_{\pm\pm\pm\pm}$, with the subscript composed of the signs of the imaginary parts of the c.m. three-momentum in the i th channel, $q_{\text{cm},i}$, from the lowest in the energy to the highest.⁴ However, in the special case when we are dealing only with quasi-bound states — unstable states that would be bound states if there were no low-lying thresholds which provide some possibility to decay — only 4 of 16 RSs are of interest because they can be reached from the physical region by crossing the unitary branch cut from $E + i\epsilon$ to $E - i\epsilon$ between the $(n-1)$ th and the n th threshold, see ref. [94] for a review. In order to simplify notation, we enumerate these RSs as follows: RS I (the physical sheet) = RS_{++++} , RS II = RS_{-+++} , RS III = RS_{--++} and RS IV = RS_{----} . As a result, in the particular case of quasi-bound states that is of interest here, the poles located on these RSs have a much shorter path to the real energies on RS I and thus have

⁴Even if some elastic channels are uncoupled, we still use the generic four-channel notation (as relevant in Schemes II and III) by assuming that the couplings to the absent channels vanish. For instance in scheme I, there are only 3, 3 and 1 elastic coupled-channels for $J = \frac{1}{2}$, $J = \frac{3}{2}$ and $J = \frac{5}{2}$, respectively, see table 1.

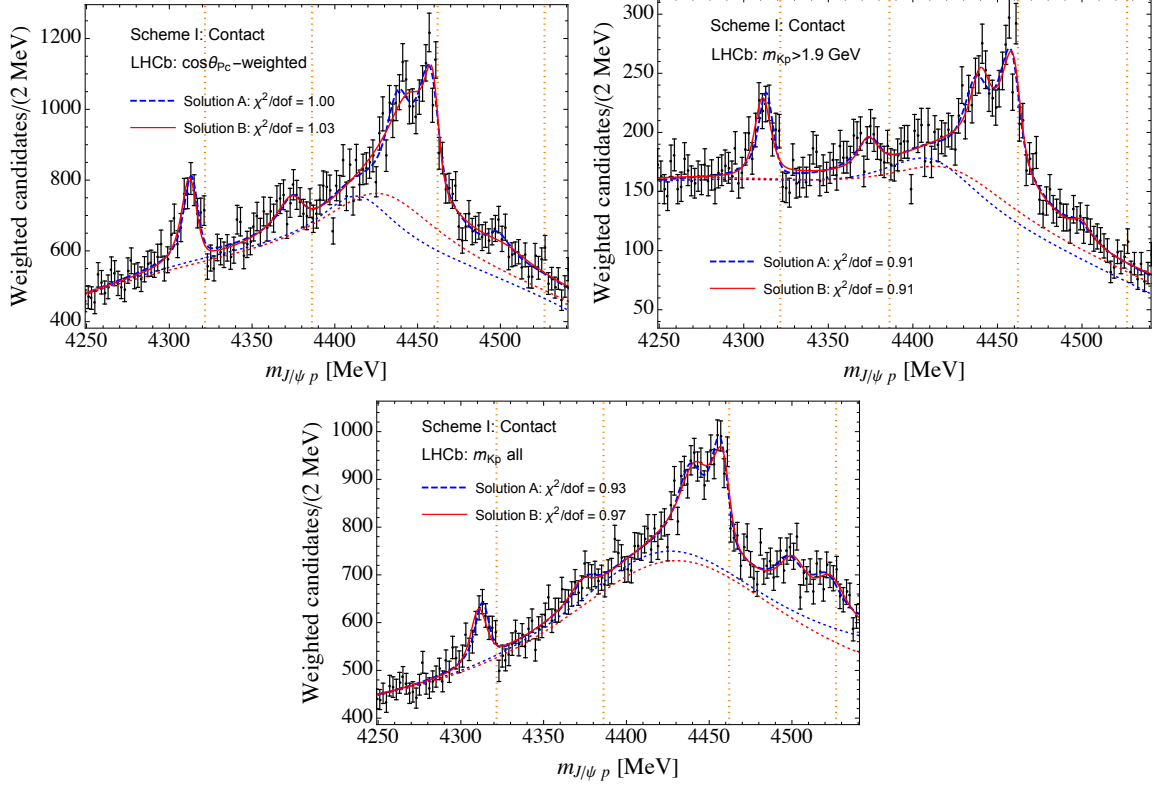

Figure 4. The best fits to the different experimental data [17] for both solution A (blue dashed curves) and solution B (red solid curves) of scheme I. The corresponding backgrounds are shown as red-dotted and blue-dotted curves, respectively. The vertical dashed lines from left to right are the $\Sigma_c \bar{D}$, $\Sigma_c^* \bar{D}$, $\Sigma_c \bar{D}^*$, and $\Sigma_c^* \bar{D}^*$ thresholds, respectively.

more significant impact on physical observables than those on the more remote sheets. We note also that when we search for the poles of the P_c 's and calculate the corresponding residues, all inelastic channels are assumed to be on the unphysical RS (−), since otherwise the poles would be remote, see ref. [80] for a detailed discussion of this case and a more general classification of the poles in the conformally mapped ω plane.

The N th RS (RS- N) can be reached from the physical amplitude T by the analytical continuation in a matrix form,

$$(T_N)^{-1} = (T)^{-1} - 2i\rho_N, \quad (4.2)$$

where ρ_N is a diagonal matrix with the first $N - 1$ elements equal to the two-body phase space factors for the corresponding channels and the others zero, i.e., $\rho_N = \text{diag}(\rho_1, \dots, \rho_{N-1}, 0, \dots)$ with $\rho_i = m_{\Sigma_c^{(*)}} m_{D^{(*)}} q_{\text{cm},i} / (2\pi E)$. Moreover, one can define the product of the effective couplings $g_\alpha g_\beta$ of a given state to channels α and β from the residue of the scattering amplitude $T_{\alpha\beta}(E)$ at the pole of that state, i.e.,

$$g_\alpha g_\beta = \lim_{E \rightarrow E_{\text{pole}}} (E^2 - E_{\text{pole}}^2) T_{\alpha\beta}(E). \quad (4.3)$$

Table 2. The names of the states, their dominant channels (DCs) and thresholds, the Riemann sheet (RS) where they lie, their quantum numbers found, the pole positions, and the dimensionless couplings to their DCs, g_{DC} , from the T -matrix residues for the solutions A and B of scheme I are given. The uncertainties stated result from taking the fit to different data and the different backgrounds used.

The two solutions produce different values of the parameters, which are given in table 4 in appendix B, in particular $C_{\frac{1}{2}}$ and $C_{\frac{3}{2}}$, and thus give different pole locations. Both solutions give seven poles in the $\Sigma_c^{(*)} \bar{D}^{(*)}$ amplitudes, i.e., seven P_c states: three with $J = 1/2$, three with $J = 3/2$ and one with $J = 5/2$. The pole positions, the dominant channels (DCs) having the largest effective couplings and lying closer to the corresponding pole, and the effective couplings of those for solutions A and B are listed in table 2. In both solutions, among the seven poles, the lowest one corresponds to the $P_c(4312)$ with $J^P = \frac{1}{2}^-$. It appears as a $\Sigma_c \bar{D}$ bound state, located on the physical RS for the elastic channel and on the unphysical RS for the $J/\psi p$ and $\eta_c p$ inelastic channels. It would become a true bound state, if the $J/\psi p$ and $\eta_c p$ channels were switched off. There are two $\Sigma_c \bar{D}^*$ bound states with quantum numbers $\frac{1}{2}^-$ and $\frac{3}{2}^-$, corresponding to the $P_c(4440)$ and the $P_c(4457)$, respectively, in solution A and with the quantum numbers interchanged in solution B , as that in ref. [40]. The interchange of the spin assignments for the $P_c(4440)$ and $P_c(4457)$ in the two solutions is a result of the proximity of the values of $C_{\frac{1}{2}}$ ($C_{\frac{3}{2}}$) in solution A to those of $C_{\frac{3}{2}}$ ($C_{\frac{1}{2}}$) in solution B , see e.g. table 4 in appendix B. There are three P_c states dominated by the $\Sigma_c^* \bar{D}^*$ channel with quantum numbers $\frac{1}{2}^-$, $\frac{3}{2}^-$, and $\frac{5}{2}^-$. Analogous to that of the $\Sigma_c \bar{D}^*$ channel, the mass pattern of the three P_c states is $m_{\frac{1}{2}^-} < m_{\frac{3}{2}^-} < m_{\frac{5}{2}^-}$ for solution A and the opposite, i.e., $m_{\frac{1}{2}^-} > m_{\frac{3}{2}^-} > m_{\frac{5}{2}^-}$ for solution B . The narrow state $P_c(4380)$, required by HQSS, with $J^P = \frac{3}{2}^-$ predicted in refs. [26, 32, 40, 46] is found around 4.38 GeV in both solutions. As a consequence of HQSS, it is as narrow as the other three P_c states (see e.g. table 2) and different from the broad $P_c(4380)$ reported by LHCb in 2015 [14]. The effective couplings of the P_c states to the nearby elastic channels are dominant though the effects from the other elastic channels are not negligible and in some cases reach up to 30% of the dominant one, see tables 8 and 9 in appendix C.

4.1.2 Predictions for the line shapes

With the parameters extracted from fits to the $J/\psi p$ channel and under the assumption that production of the inelastic channels goes through the elastic ones, i.e., $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K^-$, one can predict line shapes for other channels. This is particularly interesting because the two solutions found here correspond to different heavy-light spin structure decompositions of the higher P_c states. They are expected to have distinct consequences in their decays into channels other than the $J/\psi p$ whose s_Q is 1. Consequences of HQSS on the decays of P_c states into the $\Lambda_c \bar{D}^{(*)}$ and $\eta_c p$ considering only S -waves have been reported in refs. [31, 32]. The results below on these channels go beyond the previous results in giving line shapes, instead of ratios of partial widths, and including D -waves.

Among all possible decay channels other than the $J/\psi p$ of the P_c states, the $\Sigma_c^{(*)} \bar{D}^{(*)}$ are of particular interest since their thresholds are close to the P_c states and are sensitive to their nature [59]. One can predict the line shapes of the $\Sigma_c^{(*)} \bar{D}^{(*)}$ mass distributions from the decay $\Lambda_b \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K$. They are shown in figure 5. The existence of S -wave bound states below the thresholds leads to several manifestations in the line shapes. First, one sees the threshold enhancements for the line shapes of the $\Sigma_c^{(*)} \bar{D}^{(*)}$ mass distributions. The threshold enhancement above the threshold of the $\Sigma_c \bar{D}$ is due to the $P_c(4312)$, and that of the $\Sigma_c^* \bar{D}$ is due to the narrow $P_c(4380)$. Second, the $P_c(4440)$ and $P_c(4457)$ show prominent signals in the $\Sigma_c \bar{D}$ and $\Sigma_c^* \bar{D}$ invariant mass distributions only if they couple to these channels in S waves. Indeed, the $J = 1/2$ $P_c(4440)$ ($P_c(4457)$) and the $J = 3/2$ $P_c(4457)$ ($P_c(4440)$) are clearly seen in the $\Sigma_c \bar{D}$ and $\Sigma_c^* \bar{D}$ invariant mass distributions for solution A (B), respectively. These observations can be used to single out the unique solution from the two once data in these channels become available. Furthermore, since there are no $J = 3/2$ elastic channels below the $\Sigma_c^* \bar{D}$ threshold, the $J = 3/2$ $\Sigma_c^* \bar{D}$ molecular state $P_c(4380)$ can only manifest itself as a threshold enhancement in the $\Sigma_c^* \bar{D}$ channel but not as peaks in the other elastic channels. The higher P_c states show up as structures in all channels for both solutions though the strength of the peaks is quite uncertain and depends on the data set used in fits. This should not come as a surprise given that the shape and the relative strength of the peaks vary quite significantly in three data sets by LHCb. Specifically, the data set “ m_{Kp} all” shows some hints for the existence of the higher resonances near 4.5 GeV while the other two data sets do not, see appendix C for more details on the effective couplings to the source.

With the parameters extracted from fits to the $J/\psi p$ channel and under the assumption that production of the inelastic channels goes through the elastic ones, i.e., $\Lambda_b^0 \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)} K^- \rightarrow \eta_c p K^-$, one can also predict line shapes for the $\eta_c p$ channels. In figure 6, we show predictions for the $\eta_c p$ invariant mass distributions, which also allow one to make several important observations. First, this inelastic channel shows quite pronounced signals from all P_c states observed by LHCb and their spin partners predicted in our analysis. Second, the centrifugal-barrier suppression of the D -wave coupling of $J/\psi p$ to the P_c ’s is no longer active because the $J/\psi p$ threshold is much lower than the relevant $\Sigma_c^{(*)} \bar{D}^{(*)}$ thresholds. Therefore, the coupling of the elastic channels to $\eta_c p$ in the D wave, which is related to that for $J/\psi p$ via HQSS, is of a comparable strength or even larger than

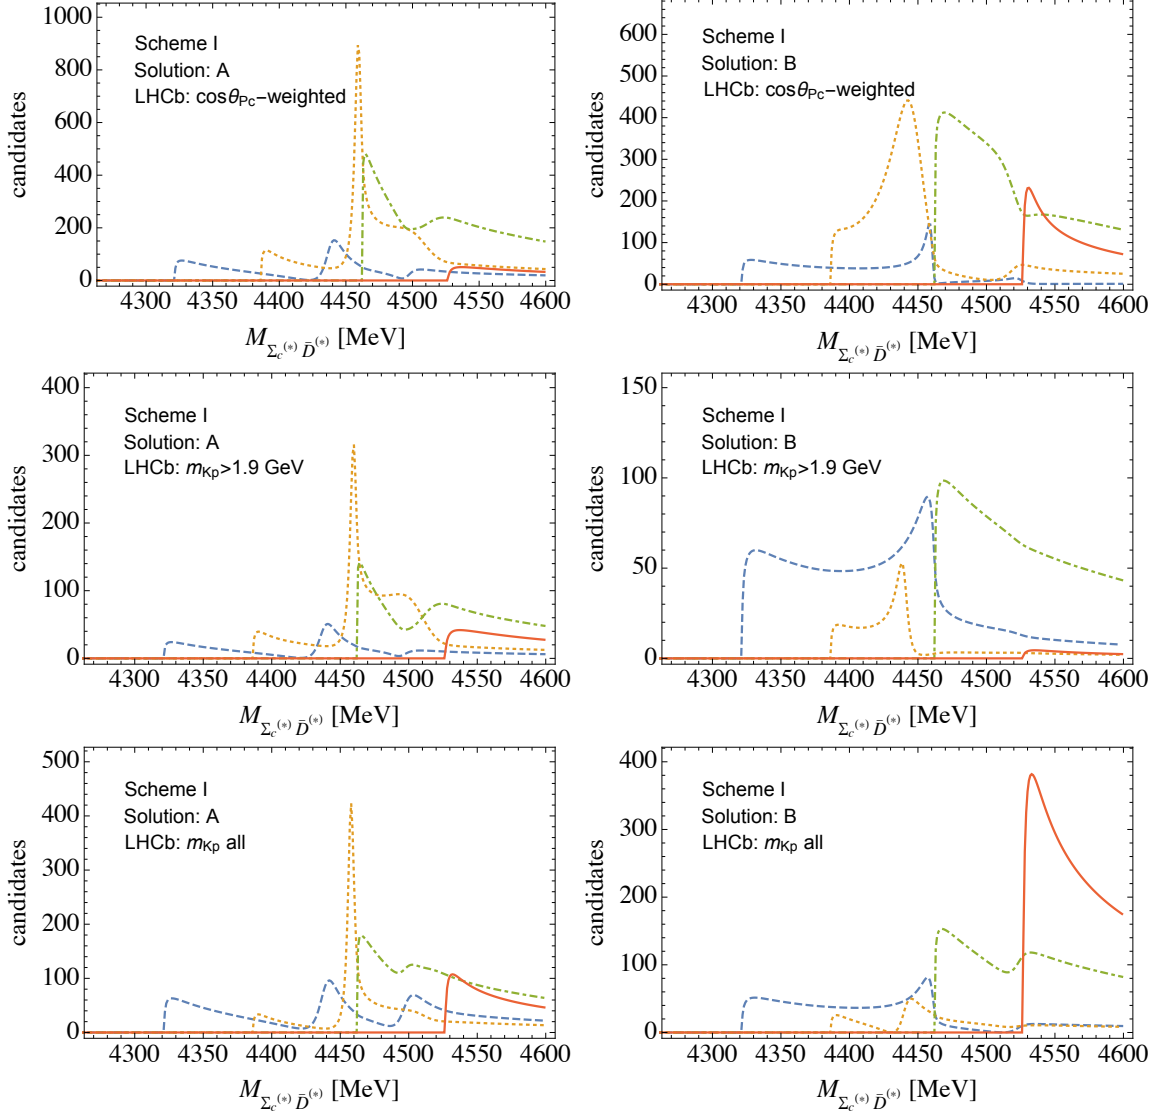

Figure 5. Predictions for the line shapes of $\Sigma_c \bar{D}$ (blue dashed curves), $\Sigma_c^* \bar{D}$ (orange dotted curves), $\Sigma_c \bar{D}^*$ (green dot-dashed curves), and $\Sigma_c^* \bar{D}^*$ (red solid curves) mass distributions based on the fit results in figure 4 for solutions A and B of scheme I without the $\Lambda_c \bar{D}^{(*)}$ channels. The qualitative differences for the higher states in various data sets are mainly caused by the different shapes of the LHCb distributions in this energy range. Note also that the background for this process is not included since it is unknown.

the S -wave coupling, as shown in table 4 in appendix B. This observation can be used to account for the fact that, contrary to the elastic channels, the $J = 3/2$ $P_c(4457)$ for solution A with its D -wave coupling to $\eta_c p$ is more pronounced in this line shape than the $J = 1/2$ $P_c(4440)$, though the latter can couple to $\eta_c p$ in S -wave. Similarly, the $J = 3/2$ $P_c(4440)$ coupled to $\eta_c p$ in D wave dominates in the line shape for solution B. Thus, the shape of the $\Sigma_c^* \bar{D}$ and $\eta_c p$ spectra provides a straightforward criterion for distinguishing between the two solutions of the simplified model including contact interactions only, in the experiment.

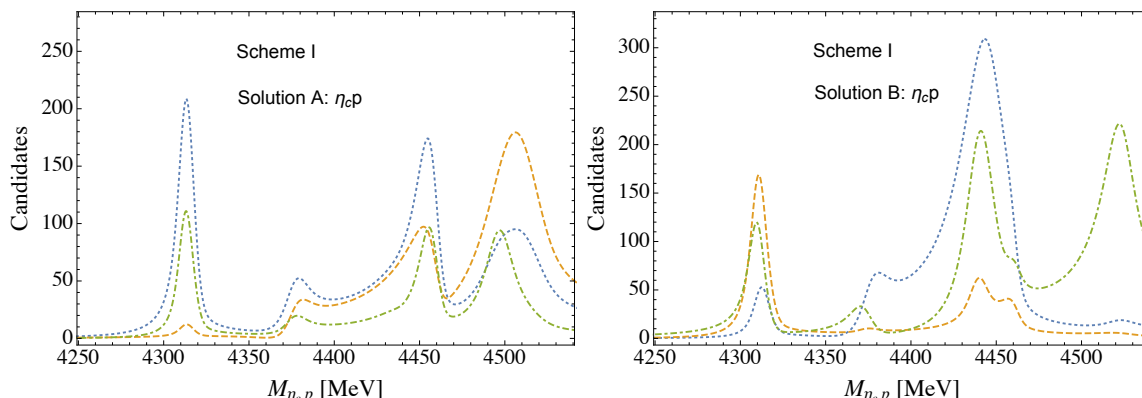

Figure 6. Predictions for the line shapes of the $\eta_c p$ invariant mass distributions based on the fit results in figure 4 for solutions A and B of scheme I without the $\Lambda_c \bar{D}^{(*)}$ channels. The blue dotted, orange dashed and green dot-dashed curves correspond to the predictions from the three fit results ($\cos \theta_{P_c}$ -weighted, $m_{Kp} > 1.9$ GeV and m_{Kp} -all) of figure 4, in order. The contribution from background is not included.

4.2 Scheme II: including the OPE potential

The importance of the OPE potential is well known for the nucleon interaction as its tensor force leads to the mixing between the S and D waves and can leave a significant impact on the line shapes. In this section, we investigate the role of the OPE for the elastic channels without considering the $\Lambda_c \bar{D}^{(*)}$ channels under the assumption that the widths of the P_c states are saturated by the $J/\psi p$, $\eta_c p$ and elastic channels. We also note that the inclusion of the OPE potential does not involve any additional parameters, see section 2.2 for the discussion of the coupling constants used, however, it calls for the inclusion of the S - D counter terms that come with unknown strengths.

4.2.1 How to renormalize the OPE and the role of S - D transitions

As noticed in refs. [73, 77], because of the large mass of the heavy system and the large splittings between the thresholds treated dynamically, the typical involved momenta are much larger than those for low-energy two-nucleon scattering, e.g., in the deuteron. In our case, the typical momenta $p_{\text{typ}} \sim \sqrt{2\mu\delta}$, with δ and μ the largest threshold splitting and the reduced mass of the system, are about 670 MeV when the energy range between the $\Sigma_c^{(*)} \bar{D}^{(*)}$ thresholds is considered and can reach 900 MeV when the energy is extended down to the $\Lambda_c \bar{D}$ threshold. These large typical momenta make the contribution from the tensor force of the OPE that leads to the S - D transitions even more important than that in the NN case, as it was already pointed out in similar studies of the $X(3872)$ and Z_b systems [73, 77]. In previous studies, the iteration of such a potential within the integral equations was shown to yield a strong regulator dependence for the observable quantities in the b -quark sector [79, 80]. This is also what we observe in the current study, as can be seen from the left panel in figure 7. In line with ref. [40], once the OPE is included, only solution B survives when the cutoff Λ in the LS equations is varied from 0.8 to 1.1 GeV. Although the χ^2/dof changes barely with the cutoff variation, a closer look into the line

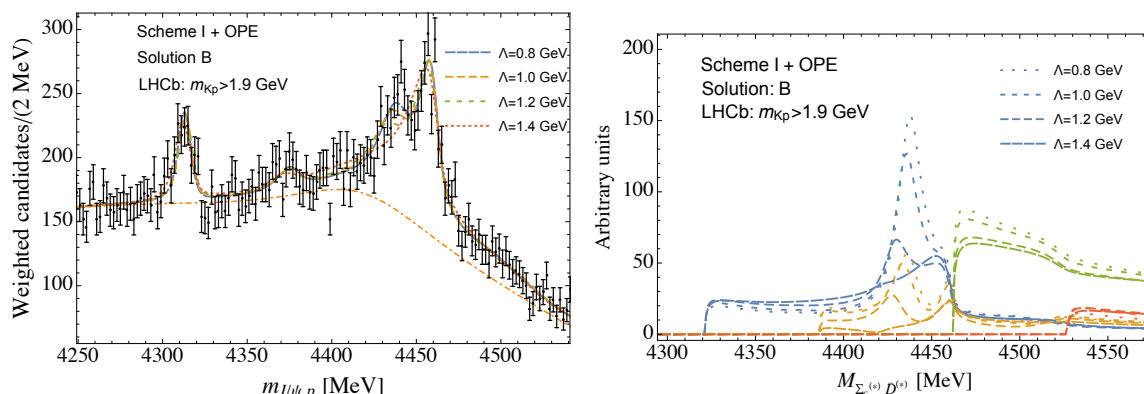

Figure 7. Left panel: best fit results for different cutoffs Λ using a potential of scheme I plus OPE in the elastic channels. Only solution *B* exists in this case. The background is shown as the orange dot-dashed curve. Right panel: predictions for the line shapes of the $\Sigma_c \bar{D}$ (blue), $\Sigma_c^* \bar{D}$ (orange), $\Sigma_c \bar{D}^*$ (green), and $\Sigma_c^* \bar{D}^*$ (red) mass distributions (background is not included).

shapes in figure 7 shows visible deviations in the results: indeed, the peak corresponding to the $P_c(4440)$ disappears in the results with increasing the cutoff. Moreover, the difference in the predicted line shapes — see the right panel in figure 7 — becomes even more pronounced, in line with the observations of ref. [80]. In particular, the disappearance of the $P_c(4440)$ in the $J/\psi p$ spectrum for $\Lambda = 1.3$ GeV leads to the same effect in the $\Sigma_c \bar{D}$ and $\Sigma_c^* \bar{D}$ line shapes in figure 7.

In order to cure the cutoff dependence, caused by the short-range part of the S - D OPE transitions, it was suggested to promote the formally NLO $O(Q^2)$ S - D contact terms⁵ to LO [79, 80]. Here, we follow the same procedure, namely we include the S - D contact terms in the elastic channels (D_b^{SD} terms in eq. (2.28)) together with the OPE. In what follows, this formulation will be referred to as scheme II. As expected, the line shapes obtained for solution *B* within scheme II, as shown in the right panel of figure 8, demonstrate only a milder regulator dependence, especially for cutoffs $\Lambda > 1$ GeV, which provide a larger separation between the soft and hard scales. More importantly, the line shapes predicted in the elastic and inelastic channels also exhibit a very mild regulator dependence (see the second and third rows in the right panel in figure 8). We expect that the residual cutoff dependence can be further reduced if the S -wave momentum dependent $O(Q^2)$ contact terms are added, in line with a related study of ref. [80]. Since these contact terms obviously cannot be fixed on the basis of current data, further studies of the regulator dependence within scheme II will be postponed to future work when new data become available.

In addition to solution *B*, in scheme II there is in principle also the best fit corresponding to solution *A* with the comparable χ^2/dof at least for smaller cutoffs. The corresponding results are shown in the left panel in figure 8. However, a closer look into the $J/\psi p$ line shape in figure 8 shows a clear cutoff dependence, making the peak from $P_c(4440)$ hardly visible for cutoffs greater than 1.5 GeV. This observation finds quantitative support in the values of the χ^2/dof , which grow with the cutoff and quickly become larger than the those for solution *B*. For example, for the cutoff $\Lambda = 1.3$ GeV the χ^2/dof values are 1.01 and

⁵ Q denotes the soft scale for the given system.

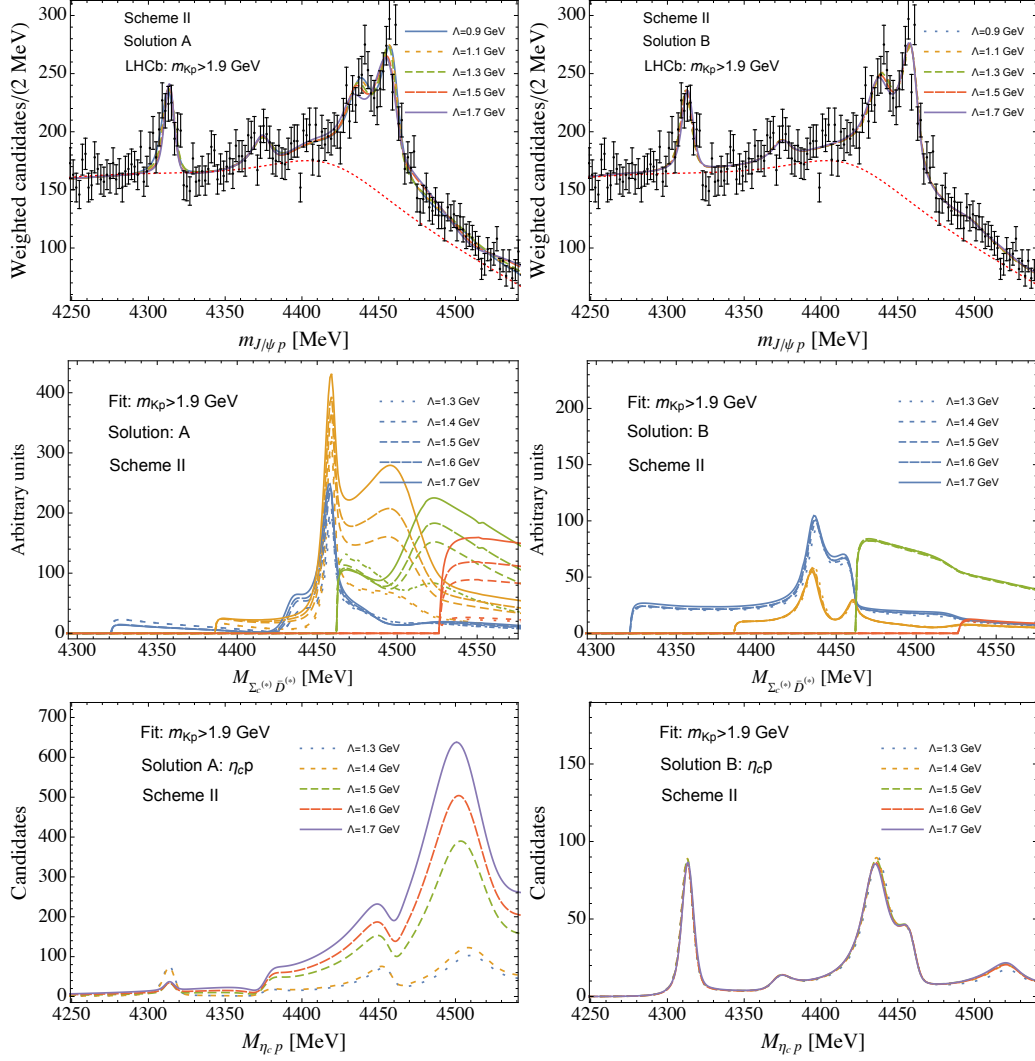

Figure 8. First row: best fit results for solutions A (left) and B (right) for different cutoffs Λ using a potential of scheme II. The background is shown as red-dotted curve. Second row: cutoff dependence of the predicted line shapes of $\Sigma_c \bar{D}$ (blue), $\Sigma_c^* \bar{D}$ (orange), $\Sigma_c \bar{D}^*$ (green), and $\Sigma_c^* \bar{D}^*$ (red) mass distributions. Third row: cutoff dependence of the predicted line shapes for the $\eta_c p$ mass distributions. No background is included for predicted line shapes.

0.90 for solutions A and B, respectively. This pattern is actually not surprising: given that solution A does not exist as long as the OPE is included but the S - D contact terms are switched off, the possibility to have a solution A in scheme II could be achieved only with the unnaturally large S - D transitions generated by the contact interactions in an attempt to improve the description of the data. Accordingly, in such an unnatural scenario, which would violate the power counting, the cutoff dependence can not be properly absorbed into redefinitions of the contact terms and reveals itself in the line shapes, especially for the predicted mass distributions in the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\eta_c p$ channels, as seen from figure 8. Therefore, we discard this scenario and in what follows focus on the results for solution B.

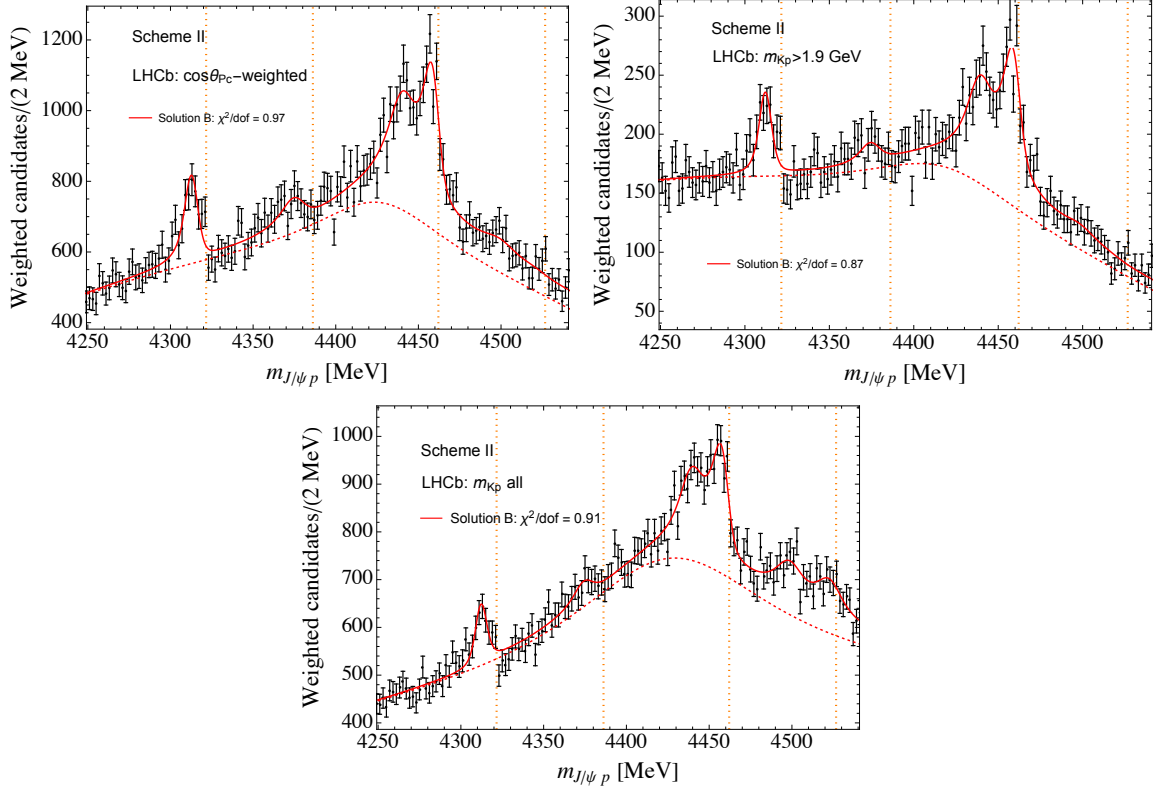

Figure 9. The best fits to the different experimental data [17] for solution B (red solid curves) of scheme II. The corresponding backgrounds are shown as red-dotted curves. The vertical dashed lines from left to right are the $\Sigma_c \bar{D}$, $\Sigma_c^* \bar{D}$, $\Sigma_c \bar{D}^*$, and $\Sigma_c^* \bar{D}^*$ thresholds, respectively.

Since the focus of the discussion above in section 4.2 was put on the renormalization of the OPE, the results presented in figures 7 and 8 were obtained using some fixed background. It is also worth mentioning that while the separation of scales calls for larger cutoffs, the cutoff larger than the c -quark mass, $m_c \simeq 1.5$ GeV, may introduce additional HQSS breaking effects.

4.2.2 Description of the data in $\Lambda_b^0 \rightarrow J/\psi p K^-$

In ref. [40], it was found that the inclusion of the OPE singles out a unique solution (the solution B) from the two almost equivalent ones present for the pure contact potentials. However, no effects from the S - D contact terms were taken into account which, as shown in the previous section, does not meet the criteria of renormalizability. Here we improve on this and discuss the renormalized results as well as their implications for the predicted line shapes, as will be shown in the next section. In figure 9, we present the best fit results for solution B of scheme II for various data sets.

A general feature of both schemes I and II is that the source couplings P_α^J are badly determined, especially for those of the three $\Sigma_c^* \bar{D}^*$ bound states, which are almost invisible in the line shapes, as can be seen from tables 4 and 5 in appendix B. Also, the couplings to the inelastic channels have sizeable uncertainties. However, the elastic channel interactions,

| | DC ([MeV]) | RS | J^P | Pole [MeV] | g_{DC} |
|-------------|---------------------------------|-----|-----------------|--------------------|--------------------|
| $P_c(4312)$ | $\Sigma_c \bar{D}$ (4321.6) | I | $\frac{1}{2}^-$ | $4313(1) - 3(1)i$ | $2.7(2) + 0.2(1)i$ |
| $P_c(4380)$ | $\Sigma_c^* \bar{D}$ (4386.2) | II | $\frac{3}{2}^-$ | $4376(1) - 6(2)i$ | $2.8(2) + 0.0(1)i$ |
| $P_c(4440)$ | $\Sigma_c \bar{D}^*$ (4462.1) | III | $\frac{3}{2}^-$ | $4441(2) - 6(2)i$ | $3.6(2) + 0.5(2)i$ |
| $P_c(4457)$ | $\Sigma_c \bar{D}^*$ (4462.1) | III | $\frac{1}{2}^-$ | $4461(2) - 5(2)i$ | $1.9(4) + 1.2(3)i$ |
| P_c | $\Sigma_c^* \bar{D}^*$ (4526.7) | IV | $\frac{1}{2}^-$ | $4525(4) - 9(1)i$ | $1.4(3) + 0.8(5)i$ |
| P_c | $\Sigma_c^* \bar{D}^*$ (4526.7) | IV | $\frac{3}{2}^-$ | $4520(3) - 12(3)i$ | $2.4(2) + 1.0(4)i$ |
| P_c | $\Sigma_c^* \bar{D}^*$ (4526.7) | IV | $\frac{5}{2}^-$ | $4500(2) - 9(6)i$ | $4.0(5) + 0.6(2)i$ |

Table 3. The names of the states, their dominant channels (DCs) and thresholds, the Riemann sheet (RS) where they lie, their quantum numbers found, the pole positions, and the dimensionless couplings to their DCs, g_{DC} , from the T -matrix residues for the solution B of scheme II are given. The uncertainties stated result from taking the fit to different data and from the different backgrounds used. The statistical uncertainties from the fit for a given background are negligible.

i.e., $C_{\frac{1}{2}}$ and $C_{\frac{3}{2}}$, are well determined and thus the pole positions and their effective couplings to the dominant channels are quite stable for different fits, as shown in table 3. The effective couplings of the P_c resonances to all elastic channels are collected in tables 10–12 in appendix C. The two solutions lead to poles which are similar to those in scheme I (see also refs. [35, 67]). The results are insensitive to the form of the background. Similar to scheme I, the $P_c(4312)$ couples dominantly to the $\Sigma_c \bar{D}$ with $J^P = \frac{1}{2}^-$, and the $P_c(4440)$ and $P_c(4457)$ couple dominantly to the $\Sigma_c \bar{D}^*$ with quantum numbers $\frac{3}{2}^-$ and $\frac{1}{2}^-$, respectively, in solution B . They are all (quasi-)bound state poles and should be understood as hadronic molecules of the corresponding dominant channels [7]. In both schemes, there is a narrow $P_c(4380)$ with $J^P = \frac{3}{2}^-$ located at around 4.38 GeV as a $\Sigma_c^* \bar{D}$ bound state. Its width is smaller than that obtained using a constant width of $\Sigma_c^{(*)}$ in ref. [40] by about a factor of 2 (see, e.g., table I in ref. [40] for solution B). The reduction of the width obtained within our dynamical framework including a three body cut is consistent with the findings of ref. [95], where the same effect was found for the partial width $X(3872) \rightarrow D\bar{D}\pi$.

4.2.3 Predictions for the line shapes in the elastic and inelastic channels

Our predictions for the elastic line shapes within scheme II are given in figure 10. In order to see the effect from the renormalized OPE, these results should be compared to the analogous predictions for solution B of scheme I in the contact potential framework given in figure 5.

As a general pattern, the shape of the invariant mass distributions for most of the elastic channels is consistent for schemes I and II, though quantitative differences are visible. The exceptions are the line shapes in the $\Sigma_c \bar{D}$ channel, which exhibit qualitatively different behavior near the state $P_c(4440)$. The $P_c(4440)$ with $J = 3/2$ can couple to the $\Sigma_c \bar{D}$ channel only in D wave and, given that only S -wave interactions are included in scheme I, this state does not reveal itself in the $\Sigma_c \bar{D}$ line shape in this scheme. However, the $P_c(4440)$

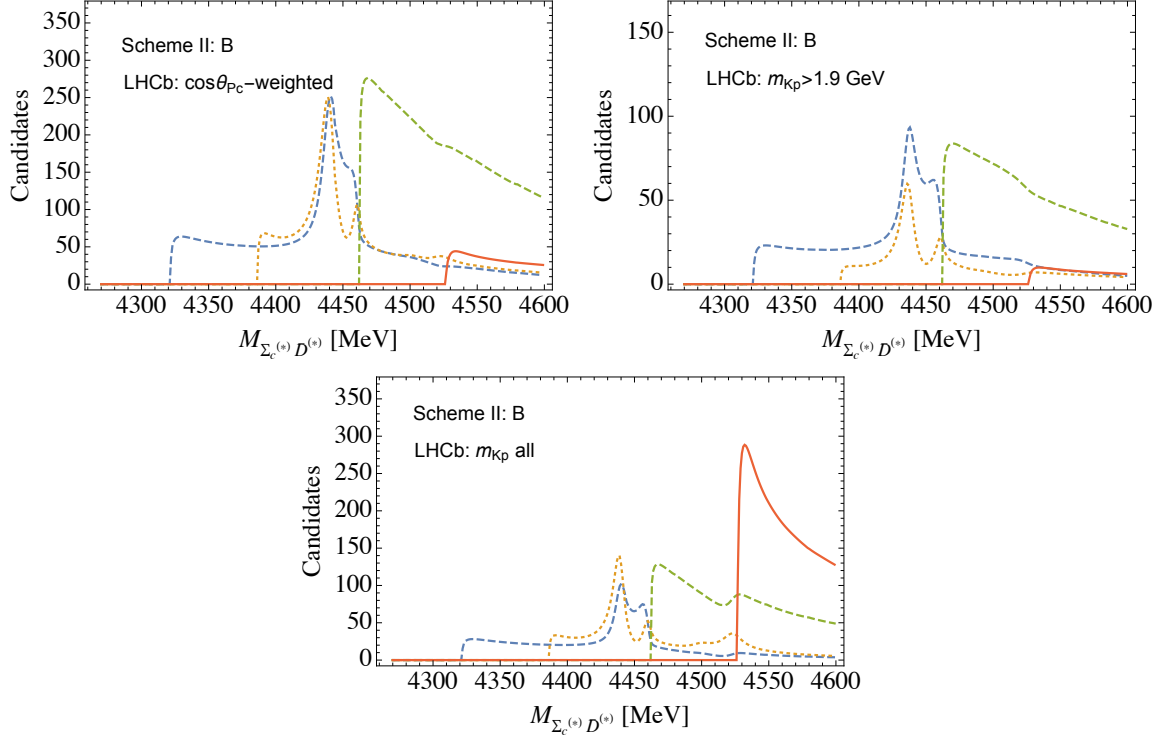

Figure 10. Predictions for the line shapes of $\Sigma_c \bar{D}$ (blue dashed curves), $\Sigma_c^* \bar{D}$ (orange dotted curves), $\Sigma_c \bar{D}^*$ (green dot-dashed curves), and $\Sigma_c^* \bar{D}^*$ (red solid curves) mass distributions based on the fit results in figure 9 for solution *B* of scheme II. See caption to figure 5 for further details.

is clearly seen in the $\Sigma_c \bar{D}$ spectrum in scheme II. This can be accounted for by the presence of the remaining *D*-wave contribution, which does not vanish after the OPE has been renormalized and thus supports the coupled-channel transitions between the dominant (*S*-wave) channel $\Sigma_c \bar{D}^*$ and the $\Sigma_c \bar{D}$.⁶ Similarly, the *D*-wave structure generated by the $J = 1/2$ $P_c(4457)$ state is seen in the $\Sigma_c^* \bar{D}$ line shape in scheme II, though it is not so pronounced as in the previous case. Clearly, it is not present in scheme I. This shows that the *D*-wave interactions in the OPE may have nontrivial consequences for the elastic line shapes. Nevertheless, all enhancements for the line shapes generated by the *S*-wave thresholds show up consistently in both Schemes. Moreover, we would like to emphasize that, as follows from table 11, by far the dominant contributions to the residues of the $P_c(4440)$ and $P_c(4457)$ states originate from the interactions in the nearby *S*-wave $\Sigma_c \bar{D}^*$ channel while the *D*-wave contributions to their residues are strongly suppressed. This picture is very natural for the molecular scenario and also finds support in a very strong enhancement of the $\Sigma_c \bar{D}^*$ line shape near its threshold in spite of the very limited phase space.

Predictions for the $\eta_c p$ invariant mass distribution within scheme II are shown in figure 11. Although the *D*-wave contributions from the OPE could bring about a visible

⁶Note that the actual strength of the *D*-wave peaks depends on the coupling constants g_1 and g_2 in eq. (2.16). While g_1 is extracted accurately from the experimental width of the $D^{*+} \rightarrow D^0 \pi^+$, g_2 was determined in a lattice QCD calculation [91] and is subject for an about 25% uncertainty not included in figure 10.

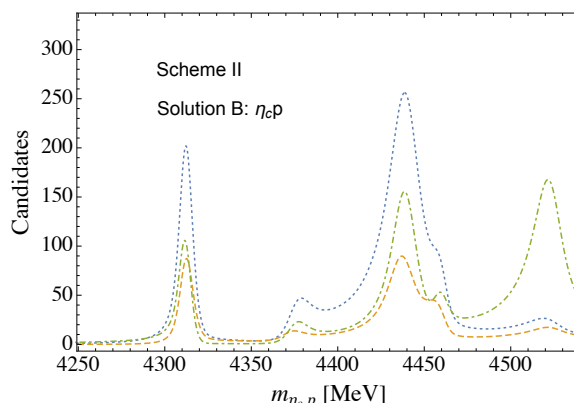

Figure 11. Predictions for the line shapes of the η_{cp} invariant mass distributions based on various fit results for solution *B* of scheme II. The blue dotted, orange dashed and green dot-dashed curves correspond to the predictions from the three fit results ($\cos\theta_{P_c}$ -weighted, $m_{Kp} > 1.9$ GeV and m_{Kp} -all) of figure 9, in order. The contribution from background is not considered.

impact on the elastic line shapes in the $\Sigma_c^{(*)}\bar{D}^{(*)}$ channels, their contributions to the η_{cp} are minor. Indeed, the D -wave contributions to the residues are strongly suppressed and the phase-space suppression, which was important for the elastic channels, does not apply any more. Accordingly, the $J/\psi p$ and η_{cp} spectra are related to each other by means of HQSS. Thus, the line shapes with and without the OPE for solution *B* are qualitatively consistent with each other, though quantitative changes in the magnitudes of the peaks are visible. For this channel it appears promising, that the first data for the reaction $\Lambda_b \rightarrow \eta_{cp} K^-$ are already available [96], although the quality of the spectra is not yet sufficient for the kind of analysis indicated above.

4.3 Scheme III: including the $\Lambda_c \bar{D}^{(*)}$ channels

As discussed in schemes I and II, the $J/\psi p$ invariant mass distribution can be well described without considering the coupled-channel effects from the $\Lambda_c \bar{D}^{(*)}$ channels and thus the widths of the P_c states can be accounted for by the channels $J/\psi p$, η_{cp} and the elastic channels. However, the lack of experimental information at present does not mean that the $\Lambda_c \bar{D}^{(*)}$ channels can be neglected. Indeed, the proximity of the $\Lambda_c \bar{D}^*$ channel to the elastic thresholds, where the P_c states reside, implies that the $\Lambda_c \bar{D}^{(*)}$ channels potentially can be even more important than the distant channels composed of a charmonium and a pion. Unlike other inelastic channels, the $\Lambda_c \bar{D}^{(*)}$ channels can couple to the elastic channels via the OPE in addition to the short-range operators, which provides further support for their potentially important role. In addition, some model calculations without the unitarity constraint concluded large branching fractions of the P_c states decaying into the $\Lambda_c \bar{D}^*$ channel [36, 97]. As discussed above, as the $\Sigma_c^{(*)}$ states dominantly decay to $\Lambda_c \pi$, the simultaneous inclusion of the $\Lambda_c \bar{D}^{(*)}$ channels and the OPE potential will lead to $\Lambda_c \bar{D}^{(*)} \pi$ three-body cuts,⁷ when the energy goes above the corresponding three-body threshold.

⁷Strictly speaking, $\Lambda_c \bar{D}^* \pi$ is a four-body state, since D^* can decay to $D\pi$. However, neglecting this width which is tiny, i.e., under the assumption that the D^* is a stable particle, that we use here, $\Lambda_c \bar{D}^* \pi$ corresponds effectively to a three-body channel.

Therefore, once the $\Lambda_c \bar{D}^{(*)}$ channels are included one is also in a position to investigate the effects from the associated $\Lambda_c \bar{D}^{(*)} \pi$ three-body cuts on the line shapes and the P_c states.

Considering these points as a motivation, we developed a coupled-channel framework that incorporates the $\Lambda_c \bar{D}^{(*)}$ channels explicitly including the OPE. While the currently available data do not allow us to adjust the parameters in the $\Lambda_c \bar{D}^{(*)}$ potentials reliably, this framework, being the most advanced and well defined formulation of the relevant coupled-channel problem on the market, should be very useful in the future in revealing the role of $\Lambda_c \bar{D}^{(*)}$ in the formation of the P_c states and their decays. It should be mentioned that preliminary LHCb data on the $\Lambda_b^0 \rightarrow \Lambda_c^+ \bar{D}^0 K^-$ are already available, but the statistics is not high enough to see clear P_c signals [98].

4.3.1 Parameters in the fits

As discussed in scheme II, because of the large mass of the heavy system and the large splittings between the dynamic thresholds, the typical involved momenta p_{typ} can reach up to 900 MeV when the energy is extended down to the $\Lambda_c \bar{D}$ threshold. These large typical momenta make the contribution from the tensor force of the OPE that leads to the S - D transitions even more important than that in scheme II. As a result, to obtain regulator-independent line shapes, promoting the formally NLO $O(Q^2)$ S - D contact terms (see D_b^{SD} and D_c^{SD} in eq. (2.28)) to LO is mandatory in line with the procedure discussed in section 4.2.1.

From the currently available data it is impossible to determine the strength of the $\Lambda_c \bar{D}^{(*)} \rightarrow \Lambda_c \bar{D}^{(*)}$ interactions, i.e., $C''_{\frac{1}{2}}$. Indeed, since the effect of $\Lambda_c \bar{D}^{(*)}$ on the elastic channels appears as a combination of $C'_{\frac{1}{2}}$ and $C''_{\frac{1}{2}}$, a stronger (weaker) $\Lambda_c \bar{D}^{(*)}$ interaction can be always compensated by a weaker (stronger) transition $\Lambda_c \bar{D}^{(*)} \rightarrow \Sigma_c^{(*)} \bar{D}^{(*)}$. In addition, because there is no isospin-conserving $\Lambda_c \Lambda_c \pi$ vertex, the long-range OPE potentials for the $\Lambda_c \bar{D}^{(*)} \rightarrow \Lambda_c \bar{D}^{(*)}$ transitions vanish (see appendix A), and thus only short-ranged direct interactions could be possible. Therefore, in what follows, we use these arguments as a motivation to neglect direct interactions in the $\Lambda_c \bar{D}^{(*)}$ channels, as it was also done for other inelastic channels. This approximation can be relaxed in the future easily, once new data, e.g. in the $\Lambda_c \bar{D}^{(*)}$ channels become available. In the current study, the effect of $\Lambda_c \bar{D}^{(*)}$ channels is therefore included through their coupling to the elastic channels. The inclusion of the OPE potential will not introduce additional parameters as the coupling constants are either fixed from experimental data or from lattice QCD [91]. In this case, under the assumption that the $J/\psi p$, $\eta_c p$, $\Lambda_c \bar{D}^{(*)}$ and $\Sigma_c^{(*)} \bar{D}^{(*)}$ saturate the widths of the P_c states, we have 7 parameters to describe the final state interactions:

- $C_{\frac{1}{2}}$ and $C_{\frac{3}{2}}$ in eq. (2.7) for the contact potentials among the elastic $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels;
- $C'_{\frac{1}{2}}$ in eq. (2.9) for the transition between the elastic $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels and the inelastic $\Lambda_c \bar{D}^{(*)}$ ones;
- g_S and g_D in eq. (2.28) for the S - and D -wave inelastic $J/\psi p$ and $\eta_c p$ channels;
- D_b^{SD} and D_c^{SD} in eq. (2.28), the NLO S - D contact terms, for the transitions among the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\Lambda_c \bar{D}^{(*)}$ channels.

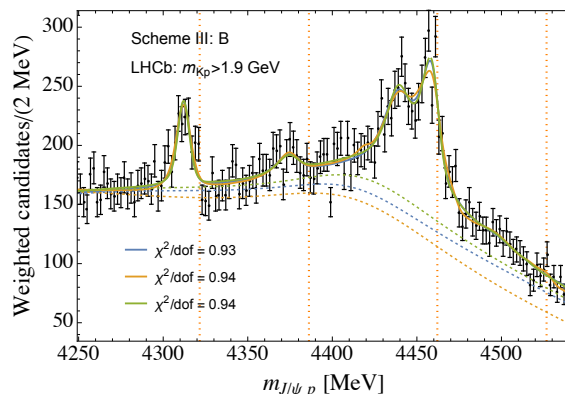

Figure 12. The best fits to the experimental data of $m_{Kp} > 1.9$ GeV [17] with three different fixed backgrounds for solution B (solid curves) of scheme III. The corresponding backgrounds are shown as dotted curves. The vertical dashed lines from left to right are the $\Sigma_c \bar{D}$, $\Sigma_c^* \bar{D}$, $\Sigma_c \bar{D}^*$, and $\Sigma_c^* \bar{D}^*$ thresholds, respectively.

In addition, there are the parameters that parametrize the background, eq. (4.1), and those of the bare production amplitudes, eq. (2.15).

4.3.2 Description of the data in $\Lambda_b^0 \rightarrow J/\psi p K^-$

There are three prominent narrow P_c structures in the $J/\psi p$ spectrum, which are used to extract the overall strength of the inelastic parameters and the production constants. As the fits without the $\Lambda_c \bar{D}^{(*)}$ channels have already yielded values for χ^2/dof less than one, it is not surprising that the explicit inclusion of $\Lambda_c \bar{D}^{(*)}$ does not improve the fit quality. As a result, the fitted inelastic parameters, as well as the bare production parameters P_α^J , are very sensitive to the data sets used in the fits and to the background employed. Indeed, as the system is overdetermined, it is hard to discriminate the contributions from the $J/\psi p$ ($\eta_c p$) and $\Lambda_c \bar{D}^{(*)}$ to the widths of the P_c states from just the $J/\psi p$ mass distributions.⁸ To illustrate this more clearly, instead of fitting to the three data sets as used in schemes I and II, we make fits to the data with $m_{Kp} > 1.9$ GeV for solution B only with three different, fixed backgrounds, as shown in figure 12. All the fits have values for χ^2/dof very close to the best fit results. However, their inelastic and bare production parameters are very different, as shown in table 6 in appendix B. Accordingly they lead to different predictions for the line shapes in the elastic and inelastic channels, as illustrated in figure 13. It follows in particular from table 6 that the product of the bare production vertices and the inelastic constants $J/\psi p$ is much better constrained by the $J/\psi p$ mass distributions than these quantities individually. For example, the fit with the background-2 (orange lines in figure 12) yields values for the $J/\psi p$ constants which are an order of magnitude smaller than for the other two fits (cf. the couplings g_S and g_D' for the fit in the middle of table 6

⁸We checked also that the inclusion of just the S -wave contact interaction $C'_{\frac{1}{2}}$ between $\Lambda_c \bar{D}^{(*)}$ and $\Sigma_c^{(*)} \bar{D}^{(*)}$ to scheme I does not allow one to reliably extract $C'_{\frac{1}{2}}$ from data.

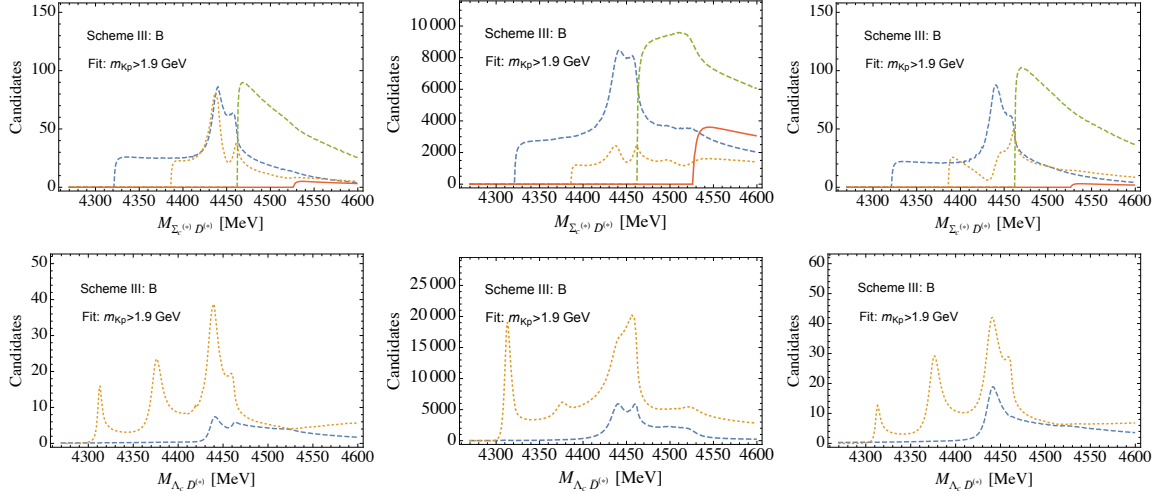

Figure 13. Predictions for the line shapes in the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\Lambda_c \bar{D}^{(*)}$ channels based on the fit results of scheme III (solution B) for three different backgrounds. The left, middle and right columns show the results that are related to the blue, orange and green lines in figure 12, respectively. First row: mass distributions in the $\Sigma_c \bar{D}$ (blue dashed curves), $\Sigma_c^* \bar{D}$ (orange dotted curves), $\Sigma_c \bar{D}^*$ (green dot-dashed curves), and $\Sigma_c^* \bar{D}^*$ (red solid curves) channels. Second row: mass distributions in the $\Lambda_c \bar{D}$ (blue dashed curves) and $\Lambda_c \bar{D}^*$ (orange dotted curves) channels. Note the different scales on the y-axes of the different plots. No contribution from a possible background is included.

with the similar couplings in other fits),⁹ which is balanced by a corresponding increase in bare production vertices. Consequently, the production rates to $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\Lambda_c \bar{D}^{(*)}$ channels for this fit are an order of magnitude larger than for the other fits, as can be seen from figure 13 (cf. the rates in the middle column with the others). Nevertheless, the results in figures allow for several constructive comments. First, we note that the line shapes in the elastic channels for background-1 are completely consistent with the corresponding line shapes of scheme II shown in figure 10. The elastic spectra for background-3 also look very similar except for the fact that the $\Sigma_c^* \bar{D}$ line shape in this case shows a dip near the $P_c(4440)$ instead of the peaks in the other cases. As discussed in section 2.1 (see the next-to-the-last paragraph), the dip in the $\Sigma_c^* \bar{D}$ line shape near the $\Sigma_c \bar{D}^*$ threshold may appear because of the destructive interference between the amplitudes in these channels. Indeed, as follows from tables 12 and 9, the bare production amplitudes $P^{\frac{3}{2}}$ from eq. (2.15) have opposite signs for the $\Sigma_c \bar{D}^*$ and $\Sigma_c^* \bar{D}$ channels for background-3, while they have the same signs for background-1 as well as in the case of scheme II. Second, since the differences in the $\Sigma_c^* \bar{D}$ channel play only a minor role for inelastic line shapes, the predicted line shapes in the $\Lambda_c \bar{D}^{(*)}$ channels in figure 13 are quite similar for backgrounds 1 and 3. Therefore, one may conjecture that, in contrast to the results for background 2, the line shapes for backgrounds 1 and 3 represent natural extensions of the results of scheme II to the full multichannel case. Then, the results for the $\Lambda_c \bar{D}^*$ spectra should have clear S -wave peaking structures

⁹In addition, we define a new parameter $g'_D = g_D k_0^2$, with $k_0 = \sqrt{\lambda(m_0^2, m_\psi^2, m_p^2)}/(2m_0)$ the c.m. momentum of the proton at the energy $m_0 = (m_{\Sigma_c} + m_{\Sigma_c^*} + m_D + m_{D^*})/2$, to allow the comparison of g_S and g'_D in the same units.

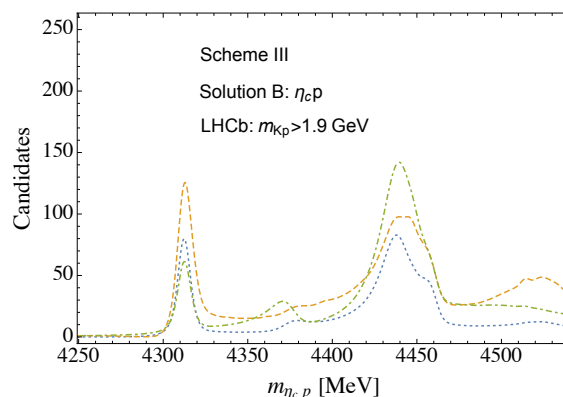

Figure 14. Predictions for the line shapes of the $\eta_c p$ invariant mass distributions based on the fit results of Scheme III (solution B) in figure 12 for three different backgrounds. The blue dotted, orange dashed and green dot-dashed curves correspond to the predictions from the three fit results in figure 12 of blue, orange and green colors, in order. No contribution from a possible background is included.

from the $P_c(4312)$, $P_c(4380)$, $P_c(4440)$ and $P_c(4457)$. In a complete analogy to the $\Sigma_c \bar{D}$ line shape (see discussion in section 4.2.3), also the $\Lambda_c \bar{D}$ spectrum shows the D -wave peak from the $P_c(4440)$. However, the $P_c(4312)$ can not be seen in the $\Lambda_c \bar{D}$ channel because the LO $\Sigma_c \bar{D} \rightarrow \Lambda_c \bar{D}$ S -wave transition potential vanishes completely (see eqs. (2.7) and (A.5)). Also, vanishing of the SD transition potential between $\Sigma_c^* \bar{D}$ and $\Lambda_c \bar{D}$, as follows from eqs. (2.28) for $V_{SD}^{\frac{3}{2}}$ and (A.6), explains why the $\Lambda_c \bar{D}$ spectrum does not show signals from the $P_c(4380)$. These are therefore testable predictions in the molecular picture which can be further updated and improved once data in these channels become available.

We stress also that the poles around the $\Sigma_c^{(*)} \bar{D}^{(*)}$ thresholds are sensitive neither to the form of the background nor to the choice of the experimental data set in the fits. The poles in scheme III are consistent with those in scheme II and thus not explicitly presented here. Also, it is worth mentioning that the line shapes in the $\eta_c p$ channels, which are related to the $J/\psi p$ distributions via HQSS, have comparable rates for all fits considered here (see figure 14). Furthermore, the shape of the $\eta_c p$ distributions is generally consistent with the predictions of schemes I and II, reported above. Specifically, the peak from the $P_c(4440)$, which is clearly seen in all line shapes for solution B, is an experimentally testable prediction.

5 Summary

In this work we present an updated coupled-channel analysis of the process $\Lambda_b^0 \rightarrow J/\psi p K^-$ for the hidden-charm pentaquark states discovered by LHCb. In ref. [40], an analysis of the $J/\psi p$ invariant mass distributions in this process was performed within a coupled-channel approach including interactions between the elastic $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels and transitions from the elastic to the S - and D -wave $J/\psi p$ inelastic channels in a way consistent with HQSS. To account for other inelastic channels not included explicitly, the LO contact interactions in the elastic channels were augmented with imaginary parts in the spirit of optical potentials. The investigation presented here improves and extends the study reported in ref. [40] in

several aspects. In particular, now we include the $\eta_c p$ and $\Lambda_c \bar{D}^{(*)}$ channels dynamically in order to restore unitarity and investigate the effect from these inelastic channels. The inclusion of $\eta_c p$ is also required by HQSS. To account for the effect of the width of $\Sigma_c^{(*)}$ in the Lippmann-Schwinger equations, the self-energy of the $\Sigma_c^{(*)}$ is considered dynamically, which generates three-body cuts from the $\Lambda_c \bar{D}^{(*)} \pi$ intermediate states. Additional three-body cut contributions appear from the transition potentials $\Sigma_c^{(*)} \bar{D}^{(*)} \rightarrow \Lambda_c \bar{D}^{(*)}$ driven by OPE. Apart from OPE, these transition potentials also involve one leading-order momentum-independent contact term as a consequence of HQSS.

We emphasize that in the fits performed in this study we take into account all the data sets of the $J/\psi p$ invariant mass distributions provided in ref. [17]. To perform the fits, we consider three strategies: employing the momentum-independent LO contact potentials without including the $\Lambda_c \bar{D}^{(*)}$ channels (scheme I), including the OPE potential supplemented by the S - D contact terms to scheme I (scheme II), and explicitly including in addition the $\Lambda_c \bar{D}^{(*)}$ channels (scheme III).

For scheme I, we assume that the widths of the P_c states are saturated by the $J/\psi p$, $\eta_c p$ and $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels. Two solutions (denoted by A and B) are found describing the data almost equally well, with χ^2 -values almost coincident to those of scheme I in ref. [40]. Both solutions give seven poles corresponding to seven P_c states. Among these states, the lowest one corresponds to the $P_c(4312)$ with $J^P = \frac{1}{2}^-$. It appears as a $\Sigma_c \bar{D}$ bound state in both solutions. There are two $\Sigma_c \bar{D}^*$ bound states with quantum numbers $J^P = \frac{1}{2}^-$ and $\frac{3}{2}^-$, corresponding to the $P_c(4440)$ and the $P_c(4457)$, respectively, in solution A and with interchanged quantum numbers in solution B , as in ref. [40]. Also the three predicted $\Sigma_c^* \bar{D}^*$ states show different mass patterns: $m_{\frac{1}{2}^-} < m_{\frac{3}{2}^-} < m_{\frac{5}{2}^-}$ for solution A and reversed for solution B . However, the three $\Sigma_c^* \bar{D}^*$ states are almost invisible in the spectra. In addition, HQSS calls for a seventh state, located close to the $\Sigma_c^* \bar{D}$ threshold with $J^P = \frac{3}{2}^-$ and with a width comparable to those of the other states. As in ref. [40], in the data we found clear evidence for this state, dubbed $P_c(4380)$, in both solutions. Testable predictions for the line shapes in the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\eta_c p$ channels are proposed. For the $\Sigma_c^{(*)} \bar{D}^{(*)}$ line shapes, the threshold enhancement at the $\Sigma_c^{(*)} \bar{D}^{(*)}$ thresholds, which is seen in these line shapes, signals the existence of the corresponding shallow bound states.

Once the OPE potentials for the $\Sigma_c^{(*)} \bar{D}^{(*)}$ channels are included in scheme II, an enhanced S -wave-to- D -wave mixing is induced leading to strongly regulator dependent line shapes. This calls for a promotion of formally NLO contact terms to LO to provide renormalization. In this way regulator-independent results for $J/\psi p$ spectra were found for solution B , while those for solution A still show a visible cutoff dependence, which becomes even stronger when the line shapes in the elastic and inelastic channels are studied. Meanwhile, solution B shows only a very mild regulator dependence for all predicted line shapes. This means that only solution B , with the $P_c(4440)$ ($P_c(4457)$) identified as a $\frac{3}{2}^-$ ($\frac{1}{2}^-$) $\Sigma_c \bar{D}^*$ bound state, survives the strong requirements of renormalizability once the OPE is included. While generally the predicted line shapes in the $\Sigma_c^{(*)} \bar{D}^{(*)}$ and $\eta_c p$ channels are qualitatively similar in both schemes I and II for solution B , the results of scheme II show also some signatures of the interactions in D -waves, which can be clearly

seen, e.g., near the $P_c(4440)$ in the $\Sigma_c \bar{D}$ spectrum. Apart from this observation, the $\eta_c p$ invariant mass distributions are very interesting since in most fits they show significant signals from the $P_c(4312)$, the $P_c(4380)$ and also from higher states around 4500 MeV. A very pronounced peak from the $P_c(4440)$ reveals itself in the $\eta_c p$ spectrum in all schemes for solution B , and therefore can be used to test the quantum numbers of the $\Sigma_c \bar{D}^*$ molecular states experimentally and thus to unravel the nature of all P_c states.

In scheme III, we developed the most advanced version of the coupled-channel approach for the pentaquark states reported by LHCb, which also incorporates the $\Lambda_c \bar{D}^{(*)}$ channels as well as the OPE. It is demonstrated, however, that, because of the lack of structures around the $\Lambda_c \bar{D}^{(*)}$ thresholds in the $J/\psi p$ channel and the absence of data in the other channels, the $\Lambda_c \bar{D}^{(*)}$ interaction strength cannot be reliably extracted from the fits to the $J/\psi p$ data only. Once new data become available, this approach should not only allow one to determine the pentaquarks quantum numbers but also to reveal their leading decay properties. Meanwhile, even based on the current data and a plausible assumption that the line shapes in the elastic channels should be qualitatively similar in schemes II and III, we make predictions for the line shapes in the $\Lambda_c \bar{D}^{(*)}$ channels which can be further updated and improved once data in these channels become available. In addition, we find that the effect of including a three-body cut from the $\Lambda_c \bar{D} \pi$ channel in the OPE potentials and especially in the self-energy $\Sigma_c^{(*)}$ in the two-body Green function reduces the width of the narrow $P_c(4380)$ by about a factor 2 compared to the one extracted using a constant complex mass of $\Sigma_c^{(*)}$ in ref. [40].

It still remains to be understood why the three P_c states near 4.5 GeV are almost invisible in the data for the $J/\psi p$ distributions,¹⁰ or why the $P_c(4440)$ and $P_c(4457)$ are more pronounced than the others. This must be related to the production mechanism, which in this work is assumed to proceed entirely through the $\Sigma_c \bar{D}^{(*)}$ channels at the primary production vertex. There can also be effects from nearby triangle singularities discussed in refs. [17, 61, 62, 64] enhancing or interfering with the production of some of the P_c states.

A One-pion-exchange potentials

Since the pion couples to the charmed mesons and baryons in the P wave, see the Lagrangian in eq. (2.16), the OPE potential mixes the S wave and D wave. To calculate the partial wave projection of the OPE potentials [99], we start from a two-body state $|JM, L\Sigma\rangle$ with J (M) the total angular momentum (its third component), L the orbital angular momentum and Σ the total spin

$$|JM, L\Sigma\rangle = \frac{1}{\sqrt{4\pi}} \sum_{\sigma_1, \sigma_2, \Sigma_3, L_3} \int d\Omega_{\mathbf{p}} Y_L^{L_3}(\Omega_{\mathbf{p}}) \langle s_1 s_2 \sigma_1 \sigma_2 | \Sigma \Sigma_3 \rangle \langle L \Sigma L_3 \Sigma_3 | JM \rangle |\mathbf{p} \sigma_1 \sigma_2\rangle, \quad (\text{A.1})$$

where $|\mathbf{p} \sigma_1 \sigma_2\rangle$ is the direct product of the one-particle states $|\mathbf{p}, \sigma_1\rangle$ and $|\mathbf{p}, \sigma_2\rangle$ with σ_i the third component of spin s_i for the i^{th} particle in that channel; \mathbf{p} is the momentum in the c.m. frame. The partial wave transition between the states with the same J and M reads

$$\begin{aligned} T_{L\Sigma, L'\Sigma'}^J &= \langle JM, L\Sigma | \hat{T} | JM, L'\Sigma' \rangle \\ &= \frac{1}{4\pi} \sum_{\sigma_1 \sigma_2 \Sigma_3 L_3} \sum_{\sigma'_1 \sigma'_2 \Sigma'_3 L'_3} \int d\Omega_{\mathbf{p}} Y_L^{L_3}(\Omega_{\mathbf{p}}) \langle s_1 s_2 \sigma_1 \sigma_2 | \Sigma \Sigma_3 \rangle \langle L \Sigma L_3 \Sigma_3 | JM \rangle \\ &\quad \times \int d\Omega_{\mathbf{p}'} Y_{L'}^{L'_3}(\Omega_{\mathbf{p}'}) \langle s'_1 s'_2 \sigma'_1 \sigma'_2 | \Sigma' \Sigma'_3 \rangle \langle L' \Sigma' L'_3 \Sigma'_3 | JM \rangle \langle \mathbf{p}' \sigma'_1 \sigma'_2 | \hat{T} | \mathbf{p} \sigma_1 \sigma_2 \rangle, \end{aligned} \quad (\text{A.2})$$

where \hat{T} is the transition operator. In the framework of the TOPT, the OPE potential acquires two contributions as shown in figure 1. For the scattering process $12 \rightarrow 1'2'$ with E the total energy of the system, and p, p' the incoming and outgoing three-momenta, we define

$$\begin{aligned} V_{SS}(E, p, p') &\equiv - \int_{-1}^1 d\cos\theta \frac{p'^2 + p^2 - 2p'p\cos\theta}{2E_{\pi}(p_{\pi})} [D_a^{\pi}(E, p, p', \theta) + D_b^{\pi}(E, p, p', \theta)], \\ V_{SD}(E, p, p') &\equiv - \int_{-1}^1 d\cos\theta \frac{4p'^2 + p^2 - 8p'p\cos\theta + 3p^2\cos(2\theta)}{2E_{\pi}(p_{\pi})} [D_a^{\pi}(E, p, p', \theta) + D_b^{\pi}(E, p, p', \theta)], \\ V_{DS}(E, p, p') &\equiv - \int_{-1}^1 d\cos\theta \frac{p'^2 + 4p^2 - 8p'p\cos\theta + 3p'^2\cos(2\theta)}{2E_{\pi}(p_{\pi})} [D_a^{\pi}(E, p, p', \theta) + D_b^{\pi}(E, p, p', \theta)], \\ V_{DD}^{(c_1, c_2, c_3, c_4)}(E, p, p') &\equiv - \int_{-1}^1 d\cos\theta \frac{c_1(p'^2 + p^2) - c_2 p'p\cos\theta + c_3(p'^2 + p^2)\cos(2\theta) - c_4 p'p\cos(3\theta)}{2E_{\pi}(p_{\pi})} \\ &\quad \times [D_a^{\pi}(E, p, p', \theta) + D_b^{\pi}(E, p, p', \theta)], \end{aligned} \quad (\text{A.3})$$

where θ denotes the angle between the three-momenta \mathbf{p}' and \mathbf{p} . The values for the c_i ($i = 1, \dots, 4$) coefficients are specified below for each value of the total angular momentum J . Moreover,

$$\begin{aligned} D_a^\pi(E, p, p', \theta) &= \frac{1}{E_\pi(p_\pi) + E_{1'}(p') + E_2(p) - E}, \\ D_b^\pi(E, p, p', \theta) &= \frac{1}{E_\pi(p_\pi) + E_1(p) + E_{2'}(p') - E} \end{aligned} \quad (\text{A.4})$$

are the contributions of the two TOPT orderings with $p_\pi = \sqrt{p^2 + p'^2 - 2pp' \cos \theta}$ and $E_i = \sqrt{p_i^2 + m_i^2}$.

The OPE potentials in the elastic channels listed in table 1 for $J^P = \frac{1}{2}^-$ can be written in a matrix form (where the columns and rows are given by the channels listed in order in table 1) as

$$V_{\frac{1}{2}^-}^{\text{OPE}} = \frac{g_1}{f_\pi^2} \begin{pmatrix} V_{\frac{1}{2}^-}^{SS} & V_{\frac{1}{2}^-}^{SD} \\ V_{\frac{1}{2}^-}^{DS} & V_{\frac{1}{2}^-}^{DD} \end{pmatrix}, \quad (\text{A.5})$$

with

$$\begin{aligned} V_{\frac{1}{2}^-}^{SS} &= \begin{pmatrix} 0 & \frac{g_2}{2\sqrt{3}}V_{SS} & \frac{g_2}{2\sqrt{6}}V_{SS} & 0 & \frac{g_3}{8}V_{SS} \\ \frac{g_2}{2\sqrt{3}}V_{SS} & \frac{g_2}{3}V_{SS} & -\frac{g_2}{6\sqrt{2}}V_{SS} & \frac{g_3}{8}V_{SS} & \frac{g_3}{4\sqrt{3}}V_{SS} \\ \frac{g_2}{2\sqrt{6}}V_{SS} & -\frac{g_2}{6\sqrt{2}}V_{SS} & \frac{5g_2}{12}V_{SS} & -\frac{g_3}{4\sqrt{2}}V_{SS} & \frac{g_3}{4\sqrt{6}}V_{SS} \\ 0 & \frac{g_3}{8}V_{SS} & -\frac{g_3}{4\sqrt{2}}V_{SS} & 0 & 0 \\ \frac{g_3}{8}V_{SS} & \frac{g_3}{4\sqrt{3}}V_{SS} & \frac{g_3}{4\sqrt{6}}V_{SS} & 0 & 0 \end{pmatrix}, \\ V_{\frac{1}{2}^-}^{SD} &= \begin{pmatrix} \frac{g_2}{4\sqrt{6}}V_{SD} & 0 & -\frac{g_2}{8\sqrt{30}}V_{SD} & -\frac{g_2}{8}\sqrt{\frac{3}{10}}V_{SD} & \frac{g_3}{16\sqrt{2}}V_{SD} \\ -\frac{g_2}{12\sqrt{2}}V_{SD} & -\frac{g_2}{8\sqrt{6}}V_{SD} & \frac{g_2}{6\sqrt{10}}V_{SD} & -\frac{g_2}{8\sqrt{10}}V_{SD} & -\frac{g_3}{16\sqrt{6}}V_{SD} \\ \frac{g_2}{48}V_{SD} & -\frac{g_2}{16\sqrt{3}}V_{SD} & \frac{7g_2}{48\sqrt{5}}V_{SD} & \frac{g_2}{8\sqrt{5}}V_{SD} & -\frac{g_3}{32\sqrt{3}}V_{SD} \\ \frac{g_3}{16\sqrt{2}}V_{SD} & 0 & \frac{g_3}{16\sqrt{10}}V_{SD} & \frac{3g_3}{16\sqrt{10}}V_{SD} & 0 \\ -\frac{g_3}{16\sqrt{6}}V_{SD} & \frac{g_3}{16\sqrt{2}}V_{SD} & -\frac{g_3}{4\sqrt{30}}V_{SD} & \frac{g_3}{16}\sqrt{\frac{3}{10}}V_{SD} & 0 \end{pmatrix}, \\ V_{\frac{1}{2}^-}^{DS} &= \begin{pmatrix} \frac{g_2}{4\sqrt{6}}V_{DS} & -\frac{g_2}{12\sqrt{2}}V_{DS} & \frac{g_2}{48}V_{DS} & \frac{g_3}{16\sqrt{2}}V_{DS} & -\frac{g_3}{16\sqrt{6}}V_{DS} \\ 0 & -\frac{g_2}{8\sqrt{6}}V_{DS} & -\frac{g_2}{16\sqrt{3}}V_{DS} & 0 & \frac{g_3}{16\sqrt{2}}V_{DS} \\ -\frac{g_2}{8\sqrt{30}}V_{DS} & \frac{g_2}{6\sqrt{10}}V_{DS} & \frac{7g_2}{48\sqrt{5}}V_{DS} & \frac{g_3}{16\sqrt{10}}V_{DS} & -\frac{g_3}{4\sqrt{30}}V_{DS} \\ -\frac{g_2}{8}\sqrt{\frac{3}{10}}V_{DS} & -\frac{g_2}{8\sqrt{10}}V_{DS} & \frac{g_2}{8\sqrt{5}}V_{DS} & \frac{3g_3}{16\sqrt{10}}V_{DS} & \frac{g_3}{16}\sqrt{\frac{3}{10}}V_{DS} \\ \frac{g_3}{16\sqrt{2}}V_{DS} & -\frac{g_3}{16\sqrt{6}}V_{DS} & -\frac{g_3}{32\sqrt{3}}V_{DS} & 0 & 0 \end{pmatrix}, \\ V_{\frac{1}{2}^-}^{DD} &= \begin{pmatrix} \frac{g_2}{24}V_{\text{DD}}^{(1,8,3,0)} & -\frac{g_2}{32\sqrt{3}}V_{\text{DD}}^{(4,23,12,9)} & -\frac{g_2}{96\sqrt{5}}V_{\text{DD}}^{(8,37,24,27)} & \frac{g_2}{32\sqrt{5}}V_{\text{DD}}^{(2,13,6,3)} & \frac{g_3}{32\sqrt{3}}V_{\text{DD}}^{(1,8,3,0)} \\ -\frac{g_2}{32\sqrt{3}}V_{\text{DD}}^{(4,23,12,9)} & 0 & \frac{g_2}{16\sqrt{15}}V_{\text{DD}}^{(1,-1,3,9)} & \frac{g_2}{32}\sqrt{\frac{3}{5}}V_{\text{DD}}^{(2,13,6,3)} & \frac{g_3}{64}V_{\text{DD}}^{(4,23,12,9)} \\ -\frac{g_2}{96\sqrt{5}}V_{\text{DD}}^{(8,37,24,27)} & \frac{g_2}{16\sqrt{15}}V_{\text{DD}}^{(1,-1,3,9)} & \frac{g_2}{120}V_{\text{DD}}^{(13,77,39,27)} & \frac{g_2}{160}V_{\text{DD}}^{(2,13,6,3)} & \frac{g_3}{64\sqrt{15}}V_{\text{DD}}^{(8,37,24,27)} \\ \frac{g_2}{32\sqrt{5}}V_{\text{DD}}^{(2,13,6,3)} & \frac{g_2}{32}\sqrt{\frac{3}{5}}V_{\text{DD}}^{(2,13,6,3)} & \frac{g_2}{160}V_{\text{DD}}^{(2,13,6,3)} & \frac{3g_2}{80}V_{\text{DD}}^{(1,9,3,-1)} & -\frac{g_3}{64}\sqrt{\frac{3}{5}}V_{\text{DD}}^{(2,13,6,3)} \\ \frac{g_3}{32\sqrt{3}}V_{\text{DD}}^{(1,8,3,0)} & \frac{g_3}{64}V_{\text{DD}}^{(4,23,12,9)} & \frac{g_3}{64\sqrt{15}}V_{\text{DD}}^{(8,37,24,27)} & -\frac{g_3}{64}\sqrt{\frac{3}{5}}V_{\text{DD}}^{(2,13,6,3)} & 0 \end{pmatrix}. \end{aligned}$$

The OPE potentials for $J^P = \frac{3}{2}^-$ read

$$V_{\frac{3}{2}^-}^{\text{OPE}} = \frac{g_1}{f_\pi^2} \begin{pmatrix} V_{\frac{3}{2}^-}^{SS} & V_{\frac{3}{2}^-}^{SD} \\ V_{\frac{3}{2}^-}^{DS} & V_{\frac{3}{2}^-}^{DD} \end{pmatrix}, \quad (\text{A.6})$$

where¹¹

$$V_{\frac{3}{2}^-}^{SS} = \begin{pmatrix} -\frac{g_2}{12}V_{SS} & -\frac{g_2}{8\sqrt{3}}V_{SS} & -\frac{\sqrt{5}g_2}{24}V_{SS} & -\frac{g_3}{12\sqrt{2}}V_{SS} \\ -\frac{g_2}{8\sqrt{3}}V_{SS} & 0 & \frac{g_2}{8}\sqrt{\frac{5}{3}}V_{SS} & \frac{g_3}{4\sqrt{6}}V_{SS} \\ -\frac{\sqrt{5}g_2}{24}V_{SS} & \frac{g_2}{8}\sqrt{\frac{5}{3}}V_{SS} & \frac{g_2}{12}V_{SS} & \frac{g_3}{12}\sqrt{\frac{5}{2}}V_{SS} \\ -\frac{g_3}{12\sqrt{2}}V_{SS} & \frac{g_3}{4\sqrt{6}}V_{SS} & \frac{g_3}{12}\sqrt{\frac{5}{2}}V_{SS} & 0 \end{pmatrix},$$

¹¹As the $V_{\frac{3}{2}^-}^{DD}$ potential is symmetric, here only the elements on the upper triangle are presented. The case is similar for the $V_{\frac{5}{2}^-}^{DD}$ potential.

The OPE potentials for the channels in order listed in table 1 for $J^P = \frac{5}{2}^-$ read

$$V_{\frac{5}{2}^-}^{\text{OPE}} = \frac{g_1}{f_\pi^2} \begin{pmatrix} V_{\frac{5}{2}^-}^{SS} & V_{\frac{5}{2}^-}^{SD} \\ V_{\frac{5}{2}^-}^{DS} & V_{\frac{5}{2}^-}^{DD} \end{pmatrix}, \quad (\text{A.7})$$

where

$$\begin{aligned} V_{\frac{5}{2}^-}^{SS} &= -\frac{1}{4}g_2 V_{SS}, \\ V_{\frac{5}{2}^-}^{SD} &= \left(-\frac{g_2}{8\sqrt{10}} - \frac{g_2}{8\sqrt{30}} - \frac{g_2}{16}\sqrt{\frac{7}{15}} - \frac{g_2}{16}\sqrt{\frac{7}{5}} \frac{g_2}{8\sqrt{15}} - \frac{g_2}{80}\sqrt{\frac{7}{3}} - \frac{g_2}{20}\sqrt{\frac{7}{2}} \frac{g_3}{16}\sqrt{\frac{3}{10}} \frac{g_3}{16\sqrt{10}} \frac{g_3}{32}\sqrt{\frac{7}{5}} \right) V_{SD}, \\ V_{\frac{5}{2}^-}^{DS} &= \left(-\frac{g_2}{8\sqrt{10}} - \frac{g_2}{8\sqrt{30}} - \frac{g_2}{16}\sqrt{\frac{7}{15}} - \frac{g_2}{16}\sqrt{\frac{7}{5}} \frac{g_2}{8\sqrt{15}} - \frac{g_2}{80}\sqrt{\frac{7}{3}} - \frac{g_2}{20}\sqrt{\frac{7}{2}} \frac{g_3}{16}\sqrt{\frac{3}{10}} \frac{g_3}{16\sqrt{10}} \frac{g_3}{32}\sqrt{\frac{7}{5}} \right)^T V_{DS}, \\ V_{\frac{5}{2}^-}^{DD} &= g_2 \begin{pmatrix} 0 & \frac{V_{\text{DD}}^{(1,5,3,3)}}{8\sqrt{3}} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{8\sqrt{42}} & 0 & \frac{V_{\text{DD}}^{(1,5,3,3)}}{8\sqrt{6}} & \frac{V_{\text{DD}}^{(2,13,6,3)}}{16\sqrt{210}} & \frac{V_{\text{DD}}^{(2,13,6,3)}}{8\sqrt{35}} & 0 & \frac{g_3 V_{\text{DD}}^{(1,5,3,3)}}{32g_2} & \frac{-g_3 V_{\text{DD}}^{(2,13,6,3)}}{32\sqrt{14}g_2} \\ \frac{V_{\text{DD}}^{(1,5,3,3)}}{12} & \frac{V_{\text{DD}}^{(2,13,6,3)}}{24\sqrt{14}} & \frac{V_{\text{DD}}^{(2,13,6,3)}}{16\sqrt{42}} & \frac{V_{\text{DD}}^{(2,13,6,3)}}{24\sqrt{2}} & \frac{-V_{\text{DD}}^{(1,5,3,3)}}{24\sqrt{2}} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{12\sqrt{70}} & \frac{V_{\text{DD}}^{(2,13,6,3)}}{8\sqrt{105}} & g_3 V_{\text{DD}}^{(1,5,3,3)} & \frac{g_3 V_{\text{DD}}^{(1,5,3,3)}}{32g_2} & \frac{g_3 V_{\text{DD}}^{(2,13,6,3)}}{32\sqrt{14}g_2} \\ \frac{-V_{\text{DD}}^{(17,100,51,36)}}{168} & \frac{-V_{\text{DD}}^{(4,5,12,27)}}{224\sqrt{3}} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{96\sqrt{7}} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{672} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{672} & \frac{-\sqrt{5}V_{\text{DD}}^{(16,83,48,45)}}{112} & \frac{\sqrt{\frac{5}{2}}V_{\text{DD}}^{(2,13,6,3)}}{112} & \frac{-g_3 V_{\text{DD}}^{(2,13,6,3)}}{32\sqrt{14}g_2} & \frac{g_3 V_{\text{DD}}^{(2,13,6,3)}}{32\sqrt{14}g_2} & \frac{-g_3 V_{\text{DD}}^{(17,100,51,36)}}{224\sqrt{3}g_2} \\ 0 & 0 & 0 & \frac{V_{\text{DD}}^{(2,13,6,3)}}{32\sqrt{21}} & \frac{V_{\text{DD}}^{(2,13,6,3)}}{112} & \frac{\sqrt{\frac{5}{3}}V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{\sqrt{\frac{5}{2}}V_{\text{DD}}^{(2,13,6,3)}}{112} & 0 & \frac{-g_3 V_{\text{DD}}^{(2,13,6,3)}}{32\sqrt{14}g_2} & \frac{g_3 V_{\text{DD}}^{(2,13,6,3)}}{32\sqrt{14}g_2} \\ \frac{5V_{\text{DD}}^{(1,5,3,3)}}{48} & \frac{-V_{\text{DD}}^{(1,5,3,3)}}{96} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{168} & \frac{-V_{\text{DD}}^{(1,5,3,3)}}{168} & \frac{-V_{\text{DD}}^{(1,5,3,3)}}{168} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{168} & \frac{-V_{\text{DD}}^{(2,13,6,3)}}{168} & \frac{-g_3 V_{\text{DD}}^{(1,5,3,3)}}{16\sqrt{2}g_2} & \frac{g_3 V_{\text{DD}}^{(1,5,3,3)}}{16\sqrt{2}g_2} & \frac{g_3 V_{\text{DD}}^{(2,13,6,3)}}{16\sqrt{2}g_2} \\ \frac{-V_{\text{DD}}^{(1,17,3,-9)}}{168} & \frac{-V_{\text{DD}}^{(1,17,3,-9)}}{168} & \frac{-V_{\text{DD}}^{(1,17,3,-9)}}{168} & \frac{-V_{\text{DD}}^{(1,17,3,-9)}}{168} & \frac{-V_{\text{DD}}^{(1,17,3,-9)}}{168} & \frac{-V_{\text{DD}}^{(1,17,3,-9)}}{168} & \frac{-V_{\text{DD}}^{(1,17,3,-9)}}{168} & \frac{-g_3 V_{\text{DD}}^{(1,17,3,-9)}}{16\sqrt{2}g_2} & \frac{g_3 V_{\text{DD}}^{(1,17,3,-9)}}{16\sqrt{2}g_2} & \frac{g_3 V_{\text{DD}}^{(2,13,6,3)}}{16\sqrt{2}g_2} \\ \frac{-V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{-V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{-V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{-V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{-V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{-V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{-V_{\text{DD}}^{(11,61,33,27)}}{112} & \frac{-g_3 \sqrt{\frac{3}{35}}V_{\text{DD}}^{(2,13,6,3)}}{16g_2} & \frac{g_3 \sqrt{\frac{3}{35}}V_{\text{DD}}^{(2,13,6,3)}}{16g_2} & \frac{-g_3 \sqrt{\frac{3}{35}}V_{\text{DD}}^{(2,13,6,3)}}{16\sqrt{35}g_2} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \end{aligned}$$

B Results of the fits

This study was performed neglecting isospin symmetry breaking effects. The masses of particles used in the calculation are [71]

$$\begin{aligned} M_{\Lambda_b^0} &= 5.6196 \text{ GeV}, & M_{K^-} &= 0.4937 \text{ GeV}, \\ M_{J/\psi} &= 3.0969 \text{ GeV}, & M_p &= 0.9383 \text{ GeV}, \\ M_{\eta_c} &= 2.9839 \text{ GeV}, & M_\pi &= 0.1380 \text{ GeV}, \\ M_{\Sigma_c} &= 2.4535 \text{ GeV}, & M_{\Sigma_c^*} &= 2.5181 \text{ GeV}, \\ M_D &= 1.8680 \text{ GeV}, & M_{D^*} &= 2.0086 \text{ GeV}, \\ M_{\Lambda_c} &= 2.2865 \text{ GeV}. \end{aligned} \quad (\text{B.1})$$

The fitted parameters to the three data of schemes I and II shown in figures 4 and 9 are collected in tables 4 and 5, respectively. We do not show the unit of \mathcal{F}_n^J because an arbitrary overall normalization factor is inseparable. The fitted parameters of the three fits of scheme III with fixed background in figure 12 are given in table 6. The parameters of the background in all fits are collected in table 7.

Table 9. The effective couplings to the elastic channels for solution *B* of scheme I, as defined in eq. (4.3).

C The effective couplings to the elastic channels and the source

The effective couplings of the P_c states to the elastic channels defined in eq. (4.3) for solutions *A* and *B* in scheme I are collected in tables 8 and 9, respectively, where the RSs on which those poles are found and the corresponding quantum numbers are given explicitly. For scheme II, the effective couplings for different quantum numbers, i.e. $J^P = \frac{1}{2}^-$, $\frac{3}{2}^-$ and $\frac{5}{2}^-$, are presented in table 10, 11 and 12, respectively.

Three experimental data sets obtained by LHCb using different kinematic selections for the candidates are employed in fits made in this analysis. It is worth mentioning, however, that the shape and the relative strength of the peaks vary quite significantly in these three data sets. Moreover, there are some hints for the existence of the higher resonances near

Table 13. The couplings of the P_c states to the source for Scheme I. They are normalized by the event numbers and thus only the relative values are meaningful. The uncertainties given are from taking different backgrounds.

4.5 GeV in the data set “ m_{Kp} all”. However, they are almost invisible for the other two data sets. Therefore, it should not come as a surprise that the effective couplings to the source also strongly depend on the input used. Their particular values are also quite sensitive to the variation of the background. For illustration, in table 13 we collect the effective couplings to the source g_{source} for scheme I defined as

$$g_\alpha g_{\text{source}} = \lim_{E \rightarrow E_{\text{pole}}} (E^2 - E_{\text{pole}}^2) U_\alpha(E). \quad (\text{C.1})$$

The uncertainties given in parentheses correspond to the different backgrounds.
